ADDRESS IN STATE MEDICINE

RECENT ADVANCES IN PREVENTIVE MEDICINE.

BY GEORGE H ROHÉ, M D

OF BALTIMORE, MARYLAND

Delivered before the Section on State Medicine of the Thirty-eighth Annual Meeting of the American Medical Association held at Chicago, June 7-10, 1887

Progress in any branch of science or art may be measured in two ways by the number and character of new discoveries made or by the gradual advances in the application of knowledge previously acquired Judged by either of these criteria the record of the past year is a creditable one to the comparatively newly cultivated field of State Medicine In the brief time at my command, I shall endeavor to sketch concisely, and in outline merely, what has been accomplished during the year in this domain

EPIDEMIOLOGY AND ENDEMIOLOGY

Adverting first to the extension of the fifth great pandemic of *Asiatic cholera*, which began in 1883, it will be seen that the danger of an invasion of this country has not yet passed, but that, on the contrary, it is greater than at any time within the last three years Both in 1886 and in the present year the disease has continued in Southeastern Italy, and in the Austrian dominions at the head of the Adriatic

In Japan the epidemic began in the summer of 1885, and after a period of cessation during the winter recurred in 1886 In the latter year there were 154,373 cases, with 101,695 deaths

In November, 1886, cholera was carried to South America, in an Italian ship, the "Perseo," bound from Genoa to Buenos Ayres The disease rapidly spread in the Argentine Republic, and crossing the Andean range invaded the Pacific coast of the South American continent

If the present geographical distribution of cholera be taken in view, it will be seen that the United States are threatened by an invasion of this disease from three sources, first, from Europe, by way of the Atlantic ocean, second, from Japan by way of the Pacific ocean, third, from the west coast of South America by way of the Pacific ocean, or by way of Mexico and our Southern border The Isthmus of Panama and the South Atlantic transportation lines may also act as gateways to the infection The present apparent lull in the activity of the disease should not tempt health authorities to relax their vigilance or neglect the precautions inculcated by sanitary science

The investigations into the etiology of cholera have proceeded on the lines marked out by Koch, in his Egyptian and Indian researches The conclusions arrived at by Dr Shakespeare, who was sent to Spain to study the disease, by the United States Government, are that the discovery of the cholera spirillum by Koch places in the hands of the profession an infallible means of diagnosis Dr Shakespeare does not commit himself to the view that the spirillum is the absolute cause of the disease The general tendency among bacteriologists is, to accept the views of Dr Koch, both in regard to the infective agent, and to the medium through which the infection gains entrance to the body, namely, contaminated food and drink Pettenkofer, however, though admitting the agency of the spirillum, still maintains the necessity of certain local and temporary conditions of soil, more particularly in relation to the movements of the ground water, in order to produce an outbreak It may be stated casually that Dr. Shakespeare reports that the results of Señor Ferrán's inoculations were more favorable than the profession were led to believe at the time they created so great a sensation

Yellow Fever appeared within the limits of the United States at only one place during the year, namely, at Biloxi, a summer resort on the Gulf coast of Mississippi The proximity of Biloxi to Ship Island, the national quarantine station, probably accounts for the appearance of the fever at the former place Prompt enforcement of sanitary measures, such as isolation of patients and disinfection of surroundings soon put an end to the outbreak

The claims of Drs Domingos Freire, of Brazil, and Carmona, of Mexico, concerning protective inoculation against yellow fever have been reiterated during the year The latest information upon this important subject available comes in the shape of a dispatch from the United States Consul at Maracaibo, Venezuela, who reports under date of March 7, 1887, that Dr Bustamente of Cucuta, Columbia, had practised inoculation with success The following quotation is from Dr Bustamente's letter "For the present I will confine myself to the statement that in more than forty persons whom I have inoculated, a fever, with many of the characteristic symptoms of yellow fever, has presented itself This fever developed by inoculation, varying several tenths of a degree, and in some cases ascending to 41° C (105 5° Fahr) but never presenting the most grave symptoms of yellow fever The result of my observations permits

me to state positively that the fever produced by inoculation is attended with no danger, and it is safe to inoculate, as I have already done, from children two years of age to the oldest individuals Many of the persons inoculated have come to this city, and in no case has the yellow fever attacked them which gives me hope of a final result completely satisfactory " Dr Bustamente also states that the municipality of Cucuta, assisted by private enterprise, has dispatched a commission, composed of two physicians, to Mexico to study the inoculation of the fever

In Brazil and Mexico the inoculations are said to amount to many thousands and complete success is claimed by Freire and Carmona and their partisans Others have, however, expressed grave doubts of the accuracy of the observations published The last Congress, recognizing the importance of a solution of this question to the people of the United States, authorized the appointment of a commission to proceed to South America and Mexico and thoroughly investigate the validity of the claims of Drs Freire and Carmona President Cleveland, with the good sense characteristic of him when dealing with scientific interests has appointed Major George M Sternberg, Surgeon U S Army, as the Commissioner to perform this duty The profession and the public may look forward with confidence to a thorough and unprejudiced investigation of the claims of Freire and Carmona Dr Sternberg sailed for Brazil on May 4, to begin his researches at the home of Dr Freire

Limited outbreaks of *small pox* occurred during the year in New York city and Brooklyn and at Los Angeles in Southern California At the latter point the disease was introduced from Mexico At present the epidemic seems to be well under control by the State Board of Health and local sanitary authorities

In this connection, reference may be made to the discussion recently re opened by Dr Fleming, the distinguished English Veterinarian seconded by the accomplished editor of the *New York Medical Journal* (Dr Frank P Foster), on the doctrine of identity of human variola and cowpox Dr Fleming believes he has shown the doctrine to be a fallacy, and in this view is strongly supported by Dr Foster According to Dr Foster, the supposed vaccinations of over three thousand persons with the virus of variolated cows, and its successive humanized cultures, made by Ceely and Badcock, of England, Adams, of Massachusetts, and Knight, of Baltimore, were merely inoculations of variolous matter which had not undergone any modification in consequence of its transmission through the bovine subject This is equivalent to saying that experienced observers as those above mentioned certainly were, are unable to perceive the the clinical difference between vaccinia and inoculation-variola From such a point of view most clinical observation could be called in question No evidence whatever is on record proving that cow-pox is anything other than variola as it affects the cow Negative testimony based upon failures to inoculate small pox virus upon cows by certain observers, can have no force in face of the comparatively numerous positive results obtained by others Cumulative increase of such negative evidence does not add to its strength

The admitted dangers of humanized vaccine from syphilis and perhaps other diseases, and the many inconveniences attending the use of bovine virus—such as prolonged incubation, untrustworthy supply, etc , have stimulated endeavors to cultivate the microbe upon which the infective power of vaccine virus may reasonably be assumed to depend In an extended series of experiments recently made, Dr John Dougall, already favorably known for his accurate work in the field of bacteriology, has attempted to secure this result but without success Where pure cultures of an organism were obtained through successive generations, it was found that the infectiveness of the microbe was lost Hence, the experiments of Dougall even failed to demonstrate whether the organisms found were specific Garré, a German bacteriologist, has also quite recently investigated the subject, with more success His pure cultures were inoculable upon animals but not upon man In the vesicles resulting from the inoculations the same organisms that composed the culture were found While these results are indefinite, they encourage us to look for success in the near future

Whether the protective power of vaccination is permanent or whether it diminishes in the course of time is still occasionally the subject of discussion in sanitary publications In recent papers Wolfiberg has carefully reviewed the entire question from various points of view, and has arrived at the conclusion that the protective influence of vaccination does not diminish, but that the natural susceptibility to small-pox increases in the human subject after the fifteenth year of life Hence, re vaccination after that age is an important safeguard The inference derived from these studies of Wolfiberg would seem to be that a thorough vaccination at or after the fifteenth year is protective for life

Scarlet Fever, one of the most fatal plagues of infantile life, has attracted especial attention in connection with the startling assertion of its apparent origin from a disease occurring in cows The evidence in support of this claim is briefly as follows Mr W H Power, of the English Local Government Board, was detailed to investigate certain outbreaks of scarlet fever, which seemed to have especial relation to the milk supply from a particular dairy farm Upon inspection this dairy was found to be in excellent sanitary condition as regards cleanliness, water supply, sewerage, etc , and for a time considerable difficulty was experienced in locating the cause of the outbreaks Improbable, as it may at first sight appear, it seems to have been incontestably established, that the epidemics of scarlatina were due to the use of milk obtained from cows attacked by a peculiar disease manifested in general by a vesicular eruption followed by ulceration of the udder The chain of circumstances connecting the disease in the cows with the outbreaks of scarlet fever in certain districts in London, supplied with milk from the diseased cows, was so strongly forged by the able investigator into whose hands the work had been committed by the authorities, that no doubt can exist that the one disease owed its origin to the other

The same outbreaks were studied by the eminent pathologist, Dr Klein, from another point of view Procuring some material from the ulcerated udders of the sick cows, he cultivated a micro organism, which, when inoculated into healthy calves, produced in them lesions similar to those existing in cows from whom the material was obtained Dr Klein has found a micrococcus presenting similar characters in the blood of scarlet fever patients Mice fed with cultures from both these sources were similarly affected From the blood of the infected mice the same micro organism was obtained and cultivated When re inoculated upon calves it produced identical lesions with the material from the diseased cows Thus the proof seems complete that a disease of cows heretofore considered unimportant is identical in nature with one of the most dreaded diseases affecting the human race That the etiological factor of scarlet fever is a bacterial organism seems also to be satisfactorily demonstrated by the researches of Dr Klein These discoveries when fully appreciated, must exert a beneficial influence upon the efforts of sanitary authorities to restrict this fatal disease A conviction of the bacterial nature of scarlet fever will tend to impress upon physicians the importance of personal measures of prevention If, as is generally assumed, the infective agent of scarlet fever is contained in the epidermis, thorough disinfection of the surface of the body will reduce the period of infectiveness of the person who has passed through an attack Instead of six to eight weeks, as now recommended, the period of isolation, when accompanied by appropriate measures of disinfection, may probably be reduced to one week after the cessation of the active symptoms This gain of time will often be a matter of great importance That even the less complete measures of isolation and disinfection heretofore practiced in certain places are effective, is demonstrated by Dr Henry B Baker, the efficient secretary of the State Board of Health He has shown most conclusively in a statistical table recently published, that the general practice of restrictive measures in scarlet fever, by the people of Michigan, since 1887, has resulted in a probable annual saving in that State of 338 lives from this one disease These results likewise show the value of an efficient, public spirited, and wide awake State Sanitary organization

Dr Baker has also recently published an abstract of his researches into the causation of *pneumonia* From a study of the meteorological conditions for a long series of years together with the varying prevalence of pneumonia, he finds that certain meteorological elements are so uniformly associated with sickness from pneumonia as to make it appear that they bear an etiological relation to that disease These meteorological elements are the amount of ozone, the temperature, the relative and absolute humidity, the velocity of the wind, and, in a measure, the atmospheric pressure Unfortunately all of these conditions are so closely related and dependent one upon another, that no one of them can be picked out as the most important factor However, Dr Baker believes that the temperature of the outside air, governing to a great degree the other meteorological conditions mentioned is the main factor to be taken into account Graphic charts which he has constructed show a very close relation between the average temperature and the sickness from pneumonia, "and the curves representing sickness from pneumonia follow uniformly at such a period after the temperature curves as to make it seem certain that the sickness is directly or indirectly caused by a comparatively low temperature"

The established relation of pneumonia morbility to a cold, dry atmosphere suggests certain measures for the prevention of the disease Such measures would be to secure to as great a degree as possible, warm, moist air for respiration How to accomplish this both within and without doors is a problem to tax the ingenuity of the practical

I may call attention also in this place to the clinical reports of outbreaks of infectious pneumonia by Graham, Lee, Thane and others, as well as to the recent researches upon the micro organism which is

A comparison of the deaths from Scarlet Fever, reported to the Secretary of State as having occurred in Michigan during the five years (1869–73) just preceding the organization of the State Board of Health, with the three years (1874–76) immediately succeeding its organization, and those three years (1874–76) with the eight years (1877–84), during which the document on Restriction of Scarlet Fever was distributed, also the five years (1869-73) just before the establishment of the Board, with the eight years (1877–84) during the use of the document, and finally, a comparison of the five years (1869–73) just preceding the work of the Board, with the eleven years (1874–84) since the State Board of Health was established

Periods of Time Compared	Estimated Average Population	Average Deaths Reported per Year	Total Reported Deaths	Average Reported Deaths per Year per 10 000 Inhabitants	Decrease of Deaths per Year per 10 000 Inhabitants	Average Decrease of Reported Deaths per Year [1]	Lives Probably Saved According to the Reports [2]
5 years 1869–73	1 215 220	589	2 945	4 85			
3 years, 1874–76	1 384 515	421	1 262	3 04	1 81	252	756
3 years, 1874–76	1,384 515	421	1,262	3 04			
8 years 1877–84	1 689 988	449	3,595	2 66	38	64	512
5 years 1869–73	1 215,220	589	2 945	4 85			
8 years 1877–84	1 689,988	449	3 595	2 66	1 19	370	2 961
5 years 1869–73	1,215 220	579	2 945	4 85			
11 years, 1874–84	1 609 023	442	4 857	2 75	2 10	338	3,718

[1] Probably not all deaths were reported before or since the organization of the Board consequently the saving is probably greater than is here shown Allowing for increase of population

supposed to be the cause of lobar pneumonia So far as the latter is concerned, pathologists have not yet arrived at unanimity Weichselbaum found organisms in every one of a series of 129 cases The microbes found were of four different forms 1 A diplococcus which seems to be morphologically and biologically identical with Sternberg's *Micrococcus Pasteuri* This was present in the lungs or sputa of 94 cases 2 A streptococcus which was found in 21 cases, none of them of the croupous, or lobar, variety 3 Staphylococcus pyogenes aureus and albus, the organisms of pus These were present in 5 cases of secondary pneumonia, and 4, a bacillus or oval micrococcus, which presents all the characteristics of Friedlander's so-called "pneumococcus," was present in only 9 of the cases[1]

Weichselbaum also confirms the statement first made by Sternberg, that organisms similar to, or identical with those found in the lungs in pneumonia (*micrococcus Pasteuri*, Sternberg) are often found in the secretions of the mouth and respiratory tract in healthy individuals Hence, while the microbes mentioned, and especially the M Pasteuri, must be looked upon as the specific agents in producing pneumonia, certain predisposing agents are necessary to enable the organisms to proliferate and produce their pathological effects The predisposing or favoring causes may perhaps be found in the atmospheric conditions claimed by Baker to stand in close relation with the prevalence of pulmonary inflammation There seems every reason to believe that a solution of this important question is near at hand[2]

The contagiousness of *tuberculosis*, and its dependence upon the bacillus discovered by Koch, seem to be so well established that rational measures for the restriction of this most fatal and universal of all pestilences should command the attention of physicians and the public It is coming to be accepted that phthisical patients should not be treated in the same hospital wards with non tuberculous individuals

A tuberculous patient in a hospital ward must be regarded as a constant focus of infection from which the disease is spread Prompt disinfection of the sputa and other discharges of the tuberculous individuals will doubtless reduce the cases by diminishing the opportunities for infection At the conference of the State Boards of Health of this country held in Toronto, last October, a resolution was adopted to the effect "that it now seems probable that progress can be made in the restriction of consumption by declaring to the people that care should be taken to destroy or disinfect the sputa from persons suffering from pulmonary consumption" This public declaration of the foremost sanitarians of America is worthy of the careful consideration of every one interested in the prevention and cure of this deadly malady

In concentrating our attention upon the pernicious effects of the bacillus tuberculosis, however, we should not lose sight of the fact that other circumstances must be considered in accounting for the origin and spread of consumption The epoch making discovery of the causal agency of soil moisture, by Dr H I Bowditch, over twenty-five years ago, is apparently confirmed by the result of a study of the topographical distribution of phthisis in Pennsylvania made by Dr William Pepper during the past year Other predisposing conditions, such as defective ventilation, insufficient or improper food, and other depressing agencies, must be admitted as at least predisposing to the development of the disease There is danger that a too exclusive attention to the microbian factors of disease will narrow our views of epidemiology and preventive medicine As there is more in pathology than the discovery and culture of bacteria, so there is more in preventive medicine than the discovery and application of microbicides

The micro organism first described in 1880 by Eberth as the cause of *typhoid fever* has now obtained general recognition, and a number of careful researches during the past year seem to have firmly established its etiological importance In a paper read before the Association of American Physicians last year, Sternberg has given a summary of all the experimental evidence available up to that time, and concludes that it is convincing as regards the etiological rôle of this bacillus

If we regard the evidence in favor of the causal relation of this microbe as sufficient, and accept the conclusions of most epidemiologists, that the typhoid poison is contained only in the intestinal discharges, and by gaining access to drinking water spreads the disease when taken into the stomach of susceptible individuals, some recent bacteriological investigations will claim our interest

Meade Bolton, Wolffhugel and Riedel, and Percy Frankland have studied the behavior of different micro organisms in water of various degrees of purity While Bolton arrived at the conclusion that pathogenic bacteria—typhoid bacillus, staphylococcus aureus, etc —rapidly lost their vitality in water, the other observers mentioned found that these organisms increased Cholera spirilli were found to become apparently acclimated to the water, and preserved their activity seven months after they were added to the water Prudden has also shown, in a recent research, that typhoid bacilli contained in water are not entirely destroyed by freezing, even after remaining in this condition for 103 days

Further, Chantemesse and Widal have recently demonstrated the presence of the typhoid bacillus in

---

1 "We may eventually find that there are various pneumonia cocci just as we have learned that the pus of acute abscesses contains sometimes one and sometimes another coccus or, again, two or more in association" Sternberg, Trans Path Soc Phila, vol xii

2 "The constant presence of this micrococcus in the buccal secretions of healthy persons, indicates that some other factor is required for the development of an attack of pneumonia and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe This supposition enables us to account for the development of the numerous attacks of pneumonia which cannot be traced to infection from without The germ being always present, auto infection is liable to occur when, from alcohol, sewer gas poisoning, crowd poisoning or any other depressing agency, the vitality of the tissues is reduced below the resisting point We may suppose, also that a reflex vaso motor paralysis affecting a single lobe of the lung, for example and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects

"Again, we may suppose that a person, whose vital resisting power is reduced by any of the causes mentioned, may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in healthy buccal secretions" Sternberg, ibid

water from a well at Pierrefonds, near Paris, which had caused a small outbreak of typhoid fever Now, these facts, taken in connection with extensive epidemics of typhoid fever, such as that occurring at Plymouth, in Pennsylvania, in 1885, which was undoubtedly traceable to infected water, point irresistibly to the conclusion that the only practical way to prevent typhoid fever is to disinfect promptly and thoroughly all the alvine discharges of the patient, before emptying them out of the vessel in which they are received During the past winter, the Committee on Disinfectants of the American Public Health Association has concentrated its labors upon the determination of the best means of destroying the typhoid infection The results of this research have not yet been published, but I am able to state that the Committee will, before the end of this year, place at command of the profession the means to absolutely prevent the spread of typhoid fever, provided the disease producing cause is developed only in the intestinal canal of those sick with this disease

PUBLIC DISINFECTING STATIONS

Disinfection, or the destruction of the infective power of infectious material occupies to day a higher place in the practical applications of preventive and curative medicine than ever before Merely referring to the exact experimental observations upon the relative value of various articles used as disinfectants, published last year under the auspices of the American Public Health Association, and to be supplemented during the present year by some very important results, I would call attention to the establishment of public disinfecting stations, as lately put in operation in some European cities In Berlin Dusseldorf, Gottingen, Strasburg, Breslau, Leipsig and Danzig such disinfecting stations are now in use and at the command of the public, under proper official control Steam under pressure is used at most of the above as the disinfecting agent, although at some super heated steam not under pressure is employed Sanitarians generally prefer the former Such disinfecting establishments should be established in every American city and free to everybody They should be under the control of the health authorities who should be held responsible for their proper management In all contagious and infectious diseases, all possibly infected objects should be disinfected The attending physician should decide when and for what objects disinfection is necessary If any physician fails to recognize the importance of this prophylactic measure, his record as purveyor of contagious diseases will soon become known in the community in which he practises and the intelligent portion of the public will learn to avoid him That the public are not opposed to availing themselves of the advantages of these institutions is shown by the experience of the station in Leipzig, to which articles not infected, but simply requiring cleaning, such as pillows and feather beds, were sent, because by the action of steam the elasticity of the feathers was restored Some control is therefore necessary to prevent persons using the disinfecting stations as free laundries This control is best placed in the hands of the attending physician without whose order no one should have a claim for free disinfection The physician can best decide in any case as to the necessity or non necessity of this procedure

With the definite, scientific character to which practical disinfection has of late been brought, sanitarians are beginning to consider whether quarantines of detention and observation may not be largely abandoned The success of the system of "maritime sanitation"—in other words thorough disinfection, practised at the Louisiana quarantine station under the intelligent and energetic direction of Dr Joseph Holt during the past three years, has demonstrated that quarantine must mean in the future something entirely different from what it meant in the past The quarantine of the future will not be an obstruction to commerce or a hindrance to international intercourse

M Proust has during the present year, in a paper read before the French Academy of Medicine, suggested a distinct advance in this direction He advises that in cases of outbreaks of infectious disease upon vessels disinfection should be performed on board during the voyage The patients should be promptly isolated and all infected articles disinfected by means of steam under pressure In order that this may be efficiently accomplished, every passenger vessel should have a physician subject to the orders of the Government authorities and independent of the navigation companies M. Proust points to the success of the plan proposed by him, on the "Mytho," a French transport from Tonquin, upon which cholera was stamped out by sanitary measures during the voyage

The lack of care exercised by trans Atlantic steamship companies concerning the importation of smallpox and other contagious diseases, calls forcible attention to one of the points in M Proust's paper, namely that relating to the independence of steamship physicians It is certain that if the medical officers of the trans Atlantic steamship lines derived their authority from government instead of from the steamship companies, the landing of cargoes of living small pox, yellow fever and cholera material upon our shores would be very much diminished, and inland State and City boards of health could look with more equanimity upon the sanitary shortcomings of the quarantine establishments at most of the Atlantic seaports

FINAL DISPOSAL OF GARBAGE AND SEWAGE

Intimately connected with the question of public disinfection is that of the disposal of the refuse of cities—garbage in the widest sense In this field decided advances have been made On the one hand new methods for the inoffensive destruction of city wastes have been devised, and on the other, older methods whose utility has been disputed, have had their value confirmed by a large amount of concurrent evidence

"Purification by fire" has been for some years the *mot du guêt* with many sanitarians And there can be no doubt that crematory destruction of garbage is absolute so far as noxiousness of the residue of

the material so treated is concerned But although the successful adoption of the system of garbage cremation by the municipalities of Montreal, Canada, and of Wheeling, West Virginia, has given this method a boom in State Medicine circles, it is absurd to make the claim that it is the only safe and effectual means of disposing of city offal

The final disposal of sewage (fecal matter and house wastes by the separate system of sewerage, or these *plus* storm water and street washings by the combined system) has long been an intricate problem in sanitary administration The self interest of municipal corporations that for mercenary considerations empty their refuse into a stream which may be or become the source of water supply for their neighbors must be checked We have in this country an example of the offender confessing judgment and putting a stop to the practice on the moral ground of its unrighteousness, thus proving that corporations are not always soulless

The irrigation system of sewage disposal which has steadily won favor among American sanitarians in recent years, has been greatly extended in Germany during the past year In Berlin, where it has been in operation for some time, it has given great satisfaction That portion of the city from which the sewage is carried to the irrigation fields has a population of nearly nine hundred thousand or about two-thirds of the whole The water drained from the irrigation fields is submitted to a chemical examination every month For the year ending March 31, 1885, only a single instance occurred in which the analysis showed marked pollution This was afterward ascertained to be due to too rapid percolation of the sewage at one point, resulting in a direct mingling of the sewage with the "filtered" water In 1885 there were 5,374 hectares (13,275 acres) of land used as sewage farms by the Berlin municipality The proportion of inhabitants estimated to each hectare is 240, (about 100 to the acre) At this rate the above number of acres would be nearly sufficient to dispose of the sewage of the entire population of Berlin by irrigation In Danzig, on the shores of the Baltic, where the soil is sandy, one acre suffices for the sewage of 240 people In this city sewage irrigation has been practised for fourteen years The coldest weather does not interfere with the irrigation From February 23 to March 4, 1886, the temperature varied from 21° to 13° F without checking the process of irrigation The low temperature of our winters is sometimes cited as an objection to the introduction of the irrigation system in the Northern and Western portions of the United States, but this experience of the city of Danzig, corroborated, as I am informed, by that of Pullman, in Illinois, and of other places in this country invalidates the objection

In Breslau, Germany, a city of about 300,000 inhabitants, the irrigation system has also been adopted At the close of last year about 1,600 acres of land in the vicinity of the city were under cultivation for sewage farming The system, which is being gradually extended, is very popular There are now nearly 6000 premises connected with the sewers The cost to each householder so connected, is less than the former method of removing fecal matters, and as the number of sewer connections increase, the cost to each property owner is proportionately diminished

In some other German cities, where the physical or topographical conditions render the irrigation system impracticable, chemical precipitation of the sewage is practiced Various methods of chemical purification are in use in Frankfort, Wiesbaden, Halle, Essen and Ehrenfeld, and all seem to be more or less successful Most of them have only been in operation during the past year so that nothing definite can yet be said about their ultimate success It is said that the cost per head is about the same as that of well administered irrigation fields A board of distinguished engineers has recently advised the adoption of this system by the city of Providence, Rhode Island

The principal difficulties encountered in the management of chemical purification systems are the nuisance created during the sedimentation of the solid portions, and the disposal of the manurial product to advantage The same objections are urged against the various pneumatic systems, which seem to have made no progress in the favor of sanitarians abroad during the past year

In England the irrigation system has been in use for many years and has given general satisfaction The city of Birmingham, with over 600,000 inhabitants, has adopted it, and with a daily discharge of sixteen million gallons of sewage finds an area of twelve hundred and twenty-seven acres of land "amply sufficient" for the purpose of an irrigation field The income realized during 1885 from the sale of stock and produce from the sewage farm amounted to over $100,000

POISONOUS AND ADULTERATED FOOD

The brilliant discovery of a new and very poisonous ptomaine in certain cheese by Prof Victor C Vaughan, of Michigan, several years ago has been followed by the demonstration of the same substance in ice cream, which had produced symptoms of poisoning in a large number of persons who had partaken of the cream Subsequently Dr Vaughan discovered the same poison in milk kept for a time in his laboratory On experimenting with the substance Dr Vaughan found that it reproduced itself, and hence concluded, apparently with good reason, that it was the product of some micro organism which has, however, not yet been isolated This ptomaine, which Dr Vaughan named tyrotoxicon, has also been found by Drs W K Newton and Shippen Wallace in milk which produced poisonous symptoms in seventy-three persons at a New Jersey summer resort All other sources of poisoning were rigidly excluded

Prof Shearer, chemist to the Iowa State Board of Health, has isolated this poison from samples of milk which had produced poisonous symptoms He also found the poison in the vomited matters of persons taken sick in an outbreak of milk poisoning, at Corning, Iowa

Dr Vaughan has suggested that tyrotoxicon may be the active cause of cholera infantum He has reported a case of this disease in which the agency of the poison in its causation seems very probable The matter is of such great importance in view of the immense annual mortality from cholera infantum in this country, that it deserves careful study

In this connection it may not be superfluous to point out the apparent causes of the development of the poison in milk In the outbreak studied by Drs Newton and Wallace, it was elicited that "the cows had been milked at the very unusual hours of midnight and noon, and the noon's milking—that which alone was followed by illness—was placed while hot, in the cans, and then, without any attempt at cooling, carted eight miles during the warmest part of the day in a very hot month" (August)

In view of the fact that Dr Vaughan will himself fully describe the chemical properties and physiological action of tyrotoxicon in a paper to be read before the Section on State Medicine, I may omit any further comment upon this subject here

Closely connected with this question of poisonous food is that of food and drug adulteration Many persons think that the assertions of sanitarians in regard to adulterations are overdrawn, but the experiences of the Massachusetts and New York State Boards of Health, contain evidence, not only as to the extent of the adulterations, but also that systematic inspection and analysis serve to diminish the practice Of 2858 articles of food and drugs tested in Massachusetts during the first five months of 1886, 1135 were found to be adulterated or defective Of 91 samples of "olive oil" 68 were spurious Vinegar was found to be below the legal standard of 4½ per cent of acetic acid in 69 out of 116 samples Lemperance drinks all contained alcohol, some over 40 per cent, and cures for the opium habit contained opium in nineteen cases out of twenty The last is called in the advertisement, "double chloride of gold," but the chemist sought for the precious metal in vain in the preparation Mustard was found to be adulterated 124 times out of 211 samples, white pepper, 63 times out of 128 samples, black pepper, 41 out 71, mace, 29 out of 45 Out of 9 samples of horse radish one was found to be genuine, the rest sophisticated Molasses is "doctored" with chloride of tin, which precipitates the coloring matter and leaves the syrup of a lighter color The poisonous precipitate is sold to the candy makers Every one can draw his own conclusions as to the results of this practice Citrate of iron and quinine sold in New York State contained from 3⅓ to 11¾ per cent of quinine, instead of the 12 per cent demanded by the Pharmacopœia 8 out of 21 samples examined contained less than 9 per cent and 4 had less than half the proportion required by the Pharmacopœial standard Other drugs were found similarly deficient In view of these facts is it any wonder that physicians so frequently fail to obtain the results from medicines which they had been led to expect by previous personal experience or the observation of others?

In Germany, sanitarians are demanding that the general Government shall take cognizance of this evil and establish public laboratories where analysis of suspected articles can be made, and if found sophisticated, the dealer punished In this country the good work being done by the State Boards of Massachusetts and New York should be imitated in all the other States By constantly agitating this matter, the public will finally be awakened to efficient action [8]

The question whether salicylic acid is harmful when added to alimentary substances as a preservative has been decided in the affirmative by a commission of the French Academy of Medicine Prof Brouardel, in supporting the conclusions of the commission, said that salicylic acid was most dangerous in atheromatous subjects, in old people, and in those in whom the kidneys did not act well He advised that its use as a food preservative be proscribed The Academy adopted this recommendation I have been informed that the use of salicylic acid for the above mentioned purpose is extensive in this country Health authorities might with advantage take note of the recent conclusions of foreign scientists upon this subject

PUBLIC BATHS

No argument should be necessary to show the importance of bodily cleanliness in the preservation of health Free public baths have long been advocated by sanitarians, but, except in a few places, the difficulties to their general introduction have hitherto seemed insurmountable It is easily seen that tub baths are out of the question where large numbers of people are expected to use the bathing facilities, both on account of the high first cost and the difficulties and expense of administration It is manifest, however, that public, like private, bathing institutions must make provision for individual baths Large pools, in which many persons bathe at once, fail to answer the requirements of sanitary science, or of public decency

The difficulty of furnishing an individual bath for public use was first surmounted by a French army surgeon, Dunal by name He devised a shower bath which was introduced in one of the barracks at Marseilles This was soon imitated at other military posts in France, and at present the new French military barracks are generally supplied with a modification of the Dunal shower bath In the German army the same system has been adopted, and now every German soldier in barracks is required to bathe every week, the military authorities furnishing the necessary facilities bath room, warm water, soap and towels In circulars No 4, S G O, 1871, and No 8, 1875, Dr John S Billings, U S A, recommended the introduction of suitable bathing facilities in our own army, and in the last named publication gave an

[8] In this connection I would call attention to the following official announcement found in a recent German journal It shows that a paternal government against which we are somewhat accustomed to declaim in this country may have some good points

Under the name *Warner's Safe Cure*' a brown liquid contained in flat bottles holding about 500 grammes is recommended as a remedy against kidney diseases and sold at four marks per bottle

' The official analysis and the statement of a resident apothecary who sells the preparation have shown that the article consists principally of American Wintergreen and that its highest value is not over two marks

' This notice is published for the information of the public

'The President of Police BARON VON RICHTOFEN

'Berlin, March 30, 1887

illustration of a simple but efficient bath on the Dunal system, as used in the prison at Rouen, France The suggestion has, however, never been acted upon by the U S military authorities, as the question of baths for the men is left to the discretion of the post commanders In the United States Navy, likewise, where the system could be adopted with the greatest ease, and doubtless often with benefit, no general movement toward it has been inaugurated

The amount of water necessary for a thorough cleansing effect with the German soldiers' bath does not exceed, according to the statement of Surgeon General Roth, of the German Army, two gallons With the aid of a piece of soap and a little friction, a much better cleansing is obtained than when a thirty gallon tub bath is used

It is evident that if this form of bath is the best and most economical for soldiers, it is likewise good for the civil population With this thought in his mind, Dr Oscar Lassar, of Berlin, had a bath of this sort constructed in the hygienic exposition in Berlin in 1883, where it seems to have attracted much attention and given general satisfaction In a space 16½ × 40 feet sufficient room was obtained for ten baths with all the accessories of a bath house, office, heating apparatus, drying room for towels, dressing rooms, etc At the meeting of the German Public Health Association last year, Dr Lassar urged the extension of these baths to the civil population, in order that every German, as he puts it, "may have his weekly bath" Dr Lassar found that bathing establishments accessible to the public, (not free), are distributed throughout Prussia in the proportion of one bathing place to 38,000 inhabitants

Incidentally, Dr Lassar gives an excellent illustration of the sanitary value of free baths in some industrial pursuits At the white lead works of Hospelt, in Ehrenfeld, there are eighty persons employed, who are required to bathe every week Towels, soap, and all facilities necessary are furnished by the proprietor of the works While the workmen appreciate the baths as a luxury, and make constant use of them, the proprietor reports a highly gratifying improvement in the health of the employes since their introduction In the first year of the use of the baths (1884), the number of cases of sickness was diminished 20 per cent, and in the following year the reduction seems to have reached 50 per cent Lead colic, especially, has become much less frequent than formerly In the dye works of Heyl Brothers & Co, near Berlin, the firm have constructed a public shower bath of ten rooms or "cells," which is free not only to the workmen and their families, but apparently to any one that desires to make use of it The proprietors say the baths have been of the greatest benefit to the workmen, and they express the hope that their action will be extensively imitated The municipal government of Paris has recently authorized the erection of three large public bathing establishments in that city Each of these is to contain a large covered pool, provided with constant in and outflow of water, which is to be heated to the required temperature in the winter season The prices to be charged are three cents per bath to schoolboys, five cents to school girls, and five cents to the general public One of the baths is to be more handsomely furnished and the charge will be a little higher, in order to cover the expenses of the other two The exhaust steam or condensed water from three large steam boiler plants belonging to the municipality will be used for the purpose of heating the water The item of cost, although small, will, however, limit these institutions in the good they can accomplish, looked at from a sanitary point of view

The establishment of free baths in connection with public schools was first suggested by Dr Carpenter, in 1877, but was not, so far as I am aware, put in practice until two or three years ago when the Mayor of Gottingen, the famous German University town, decided to introduce it into the schools The population of Gottingen is about 21,000, and about 3 000 children attend the public schools The baths are fitted up in the basement of one of the school-houses, where two apartments, each 8 feet 3 inches by 17 feet, were constructed, one being used as a dressing room and the other as the bath room The walls are white-coated and the floors are asphaltum The heating of the basement, and of the water required for the baths, does not add much to the expense of heating the building

The baths consist of three shower baths with shallow zinc basins, 1 metre (40″) in diameter The children are bathed during school hours, and the process requires so little time that a class of fifty can bathe in about one hour Every child attending school has the opportunity of bathing once in two weeks The children bring soap and towels with them from home The baths are in use throughout the year At first, this novel feature of school administration did not commend itself to the favor either of the children or their parents, but less than two months after the introduction of the baths, 75 per cent of the children took advantage of the opportunity offered The authorities and teachers are unanimous upon the point that the system is of great benefit to the children, not only from its direct sanitary advantage, but from the habits of cleanliness formed, to which they are likely to adhere through life

The great sanitary importance of cleanliness has led me to make some investigations into the facilities for bathing enjoyed by the working people in this country With this end in view, I addressed a circular letter to the Mayors of ninety-two cities, asking information upon the following points, viz The existence of free public bathing establishments, their number, time when open during the year, and the extent to which they are used by the public Also the total number of residences and of buildings furnished with private baths in each city From the answers received tables 1 and 2 give a summary of those available for statistical purposes From table 1 it will be seen that the bathing facilities for the lower classes are absurdly insufficient, Boston making the nearest approach to an attempt to fill the want Even here, however, the poor laborer who has no bath tub at home, and is unable to pay the charges at a public bathing establishment, is deprived of this sanitary necessity during eight months of the year

TABLE I

CITIES IN UNITED STATES HAVING FREE PUBLIC BATHS

	No of Bathing Establishments	Time during which the baths are in use	No of persons using baths
Boston, Mass	17	June 1 to Sept 30	959 765 in 1886
Brooklyn, N Y	3	June to October	275 885 in 1886
Buffalo, N Y	(1)		Not very generally used
Cleveland, O	1		Little used
Hartford, Conn	1		Very extensively used
Philadelphia, Pa	5	June 25 to Sept 26	581 771 in 1886
New York, N Y	15	June to October	3 431 086 in 1883

1 Not from official reports

TABLE II

CITIES IN UNITED STATES NOT HAVING FREE PUBLIC BATHS

	No of Houses in City	No of Homes supplied with Bath Tubs
Baltimore, Md	70 000	20 000
Bridgeport, Conn	6 000	2 000
Cambridge, Mass	9 308	2 315
Charleston, S C	10 000	500
Cincinnati, O	33 471	6 000
Lancaster, Pa	5 600	1,000
Lynn, Mass	5 800	1 238
Milwaukee, Wis	25 000	3 000
Minneapolis, Minn	17 000	3 000
New Bedford, Mass	5 237	517
Peoria, Ill	7 600	600
Portland, Me	7,188	1,153
Reading, Pa	11 000	1 900
Savannah, Ga	6 000	4 000
Somerville, Mass	2 000	500
St Louis, Mo	50 000	8 000
St Paul, Minn	30 000	10 000
Wilmington, Del.	12 000	5 000
	313 794	71,003

That a very large proportion of the inhabitants of our cities are deprived of proper bathing facilities is shown by table 2 Eighteen cities from which available statistics were received show that only about twenty three per cent of residences are supplied with bath tubs Taking into account the difference in the numbers of persons occupying houses inhabited by the poor, and by those in easier circumstances, we may estimate that five sixths of the inhabitants of these cities have no facilities for bathing except such as are afforded by pail and sponge, or a river, lake or other body of water which may be easily accessible In winter, even these sources of cleanliness are cut off

I need not detain you to point out that this absence of the facilities for keeping clean is a crying evil which demands the attention of sanitarians, physicians, and in fact, all intelligent people All are equally interested Dirt is not only a source of disease, but probably no less a factor in the promotion of crime I may quote here with my full endorsement the enlightened opinion of the Mayor of Reading, who says "I am persuaded that uncleanliness produces immorality and crime, for in proportion to the decrease of personal importance which an individuals experiences, is he lost to the legal restrictions about him Beclouded faces drive men from the light, and darkness breeds dangers of all kinds, so that apart from sanitary benefits, public baths would in my estimate reduce crime" I quote these words with the more pleasure, for public officials do not often bother their minds with sociological problems

As to the arrangement of a free public bathing establishment, I agree with Lassar that the spray bath of the Dunal type, with such modifications as a more extended experience in the German army has suggested, would better fulfil the demands of sanitarians than the pool bath so generally used in these institutions The individual spray bath is more cleansing, each person bathes in absolutely clean water—at least as pure as the supply can furnish—and the privacy secured to each bather, both in the bath and dressing room, would tend to the maintenance of morality and self respect The economy of the spray bath, both in first cost and in administration, likewise points to it as the bath of the future especially for public purposes

I would urgently press upon your attention the great sanitary and social importance of this reform.

SOME RESULTS OF SANITARY MEASURES

In determining the results of sanitary measures, errors of observation, or of inference are very liable to creep in and vitiate our conclusions However, in a number of instances, after making all reasonable allowances for such errors, we may conclude that a reduction of the usual death rate of a place following upon the enforcement of sanitary measures, and continuing during the time such measures are carried out, is fairly due to the agencies mentioned As a fit conclusion to this summary of progress, I have thought it not inappropriate to group together a number of instances where the inference that the improvement was due to sanitary measures seems justified by the evidence upon record I have already called attention to the fact that in the State of Michigan the saving of life during a period of efficient sanitary administration amounted to 3,718 lives from a single disease (scarlet fever) in eleven years, or 338 per year

In a communication to the Michigan State Medical Society on May 13, 1887, Dr Baker gives some suggestive statistics showing the results of isolation and disinfection in restricting diphtheria There were in 1886, 461 outbreaks of diphtheria in Michigan, exclusive of Detroit and Grand Rapids In 243 of these it is uncertain whether any measures of isolation or disinfection were taken In 102 outbreaks isolation and disinfection were both neglected, and in 116 outbreaks isolation and disinfection were both enforced The sequels of these outbreaks were as follows

In the total of 461 outbreaks there were 3,085 cases and 656 deaths, an average of 6 69 per cent of cases and 1 42 per cent of deaths In the 243 outbreaks where it is doubtful whether proper restrictive measures were taken, the cases were 1,103, with 250 deaths, an average of 4 54 of cases and 1 03 of deaths *In the 102 outbreaks where no measures were taken, the cases numbered 1,650 and deaths 329, an average of 16 18 per cent of cases and 3 23 per cent of deaths* Contrasted with this, we have *116 outbreaks in which both isolation and disinfection were enforced, with only 332 cases and 77 deaths, an average of 2 86 per cent of cases to each outbreak and only 66 per cent of deaths* Dr Baker points out

that according to these statistics 1,545 cases and 298 deaths from diphtheria were prevented during the year 1886, in his State If these results do not show conclusively the effects of appropriate sanitary measures, then figures are most abominable liars

In Great Britain, it is estimated by Dr Ogle that sanitary improvements have had the effect of adding 1 44 years of life to every male, and 2 77 years to every female in England and Wales, and Mr Edwin Chadwick is quoted as saying that "the changes in the death rate have given to the community an annual addition of 1,800,047 years of life shared among its members, and allowing that the changes in the death rates are the direct consequence of sanitary interference, we must regard this addition of nearly two million years as an annual income derived from the money invested in sanitation" If we put this saving of life in round numbers, we find that in the five years 1881-5, there has been an annual saving of the lives of 62,000 persons in England and Wales, which would have been lost in default of the sanitary measures enforced Capt Douglas Galton estimates the annual saving of life in Great Britain in 1880 84 at 102,240 This is on the assumption, of course, that no other causes could or did produce this saving of life It is greatly to be regretted that in this country we have no such system of vital statistics as will enable us to "take an account of stock," which would show whether we are making similar progress But, if we could do so, such a reduction in the death rate among our 60,000,000 people would show a saving of the lives of 144,000 persons per year Certainly this is worth striving for

In Holland a law to restrict the spread of infectious diseases went into effect in 1872 Comparison between the mortality before and since that year shows that there has been a decrease in the number of deaths from typhoid fever, small-pox, scarlet fever, measles and diphtheria The measures relied upon were isolation and disinfection

When we reflect that in the year 1885 there were 2,374 deaths from measles and scarlet fever in the State of New York, the inquiry presents itself forcibly whether a rigid system of notification, isolation and disinfection carried out under the authority of an efficient health officer, could not greatly reduce and in time wipe out the mortality from such purely contagious diseases

Another instance showing the effectiveness of prompt isolation and disinfection in stamping out a beginning epidemic, is afforded by the incident of the outbreak of yellow fever at Biloxi, Miss, last summer The measures taken have been already pointed out in sufficient detail on a preceding page

In my native city of Baltimore, it is claimed by the health department that certain infectious diseases have been reduced markedly since the introduction of a thorough system of plumbing inspection During the same time, however, isolation and disinfection have been more thoroughly practiced, and doubtless most of the good results are due to these features of the sanitary administration

In Memphis, which has for six years past been the cynosure of all sanitary eyes in this country, the improvements, initiated by the National Board of Health, and so efficiently carried out by the local board under the presidency of Dr George B Thornton, have resulted in reducing the total death rate from 35 per thousand to 23 80 per thousand

In this great metropolis of the West, whose bountiful hospitality we are now enjoying, I find it stated that during the last five years the death rate has decreased from 25 69 per thousand to 19 46 per thousand, an apparent net saving of 17,214 lives in that period, due probably to the enforcement of sanitary measures Other instances of the same sort could be cited I have quoted the above merely to point out the way in which, it seems to me, the practical sanitarian should direct his forces in the struggle with communicable diseases First of all the health authority must ascertain the presence and locality of every case of contagious or infectious disease This can only be done by requiring the physician to promptly report every such case that comes to his professional knowledge I am quite aware that many physicians contest the right of the State or municipality to exact compliance with laws requiring them to report such cases Some contend that such notification is a violation of professional secrecy, but the majority object because the State offers no pay for service performed The latter objection seems to me valid, physicians do not owe the State gratuitous service, any more than do other professions The ethical objection appears to me the height of absurdity I beg leave to quote upon this point the remarks of Dr Ezra M Hunt "If Boards of Health," says Dr Hunt, "have as one of their objects the prevention of the extension of communicable diseases, it would seem to follow as a corollary that they have the right to know where such diseases exist It is a parody on ethics to class as professional family secrets, the concealment from a health officer that there is small-pox in Mr A's family, or that Mr B's children are having the scarlet fever or diphtheria Nor can any judicial decision be found to sustain any, who, under the assumption of an invasion of personal rights, claim that the law has no right to obligate those in attendance upon cases of contagious disease to help guard the public health"

The *first* requirement then in dealing with infectious diseases from "a State Medicine point of view" is *notification*, and inasmuch as such notification will never be effective if voluntary, it must be made compulsory

The *second* requirement in restricting the prevalance of such diseases is the segregation of patients, and guarding healthy individuals, except the immediate attendants, from contact with them This is evident to all intelligent persons at first thought

The *third* requirement is prompt and thorough disinfection, in other words, the absolute destruction of the infective properties of infectious matter, in whatever that may consist For a number of diseases the infectious material itself, as well as the modes by which it is given off from the patient or communicated to healthy persons are known For others we may venture a probable guess

Recent studies upon disinfectants have pointed

out those which are trustworthy, and removed difficulties in their practical application

I would therefore declare the watchwords of the practical and progressive sanitarian in dealing with communicable diseases to be these three *Notification, Isolation, Disinfection*

NOTE.—Near the end of May 1887 yellow fever broke out in Key West Fla but had not assumed the dimensions of an epidemic at the date of delivery of this address

ORIGINAL ARTICLES.

ERYSIPELAS OF THE PHARYNX AND LARYNX, EPIDEMIC AND SPORADIC

BY BLDFORD BROWN, M D,

OF ALEXANDRIA VA

PRESIDENT OF THE MEDICAL SOCIETY OF THE STATE OF VIRGINIA MEMBER OF THE BOARD OF MEDICAL EXAMINERS OF VIRGINIA, AND OF THE AMERICAN MEDICAL ASSOCIATION

The etiology of this affection is somewhat obscure, and its medical literature rather scanty The disease has appeared in the United States and Europe in certain localities, both in epidemic and sporadic form Like all erysipelatous affections, it possesses contagious properties But the most frequent cause appears to be some mysterious epidemic influence which invades certain localities and sections, expends its septic properties, and probably disappears never to return in the same region In a certain limited district in my knowledge, erysipelas of the throat of a very malignant type prevailed some thirty-two years since I am not aware that it has ever returned to that particular locality

Epidemic erysipelas of the pharynx, because of the peculiar dark appearance of the tongue, has in certain districts received the appellation of "black tongue" In other localities it has popularly been termed "choke disease," because of the rapid tendency to suffocation, from the glottis and epiglottis becoming suddenly involved in the œdematous process It has also been designated by some as "malignant sore throat," because of the immense fatality attending the disease That epidemics of erysipelas attacking the throat exclusively may appear in particular districts, run their course, and finally disappear, is an occurrence which has been repeatedly witnessed At other periods, epidemics of erysipelas of the external surface may prevail, during which a limited number of cases may occur in which the disease may attack the throat alone I am inclined to the belief that an ordinary case of tonsillitis, occurring during the prevalence of a very positive tendency to epidemic erysipelas with a septic condition of the atmosphere, would very readily become septic in character and assume the form of erysipelas, just as we observe a wound become erysipelatous when a decided tendency to that type exists, and presenting what we term traumatic erysipelas

Symptoms.—In the initiatory stage of erysipelas of the pharynx, the entire mucous surface of the velum, uvula, tonsils, root of the tongue and post-pharynx is observed to be red, highly engorged, dry and puffy The distressing burning pain is usually very great The difficulty of deglutition from stiffness of the structures, even at this stage, is very considerable The rapidity of progress of the inflammatory action, swelling and œdema, from this stage, is something marvellous, and constitutes a marked and distinctive feature of the disease No other local affection within my knowledge pursues invariably so rapid a course towards a fatal termination Within from six to twelve hours the respiration becomes difficult, stertorous, and gurgling The voice at this stage becomes whispering, and then completely obliterated Then follow suffocation and death

Previous to these changes in the functions of the parts, the swelling and œdema of the structures in the pharynx, the glottis and epiglottis, assume enormous proportions The root of the tongue being also involved in the erysipelatous affection, the organ, from compression of its venous circulation, assumes a dark, livid, dry appearance, and occasionally protrudes somewhat from the mouth

The cavity of the pharynx, if any portion can be seen, is observed to be one indistinguishable red, swollen mass, without any defined boundaries, or anatomical features Under these circumstances it is impossible to obtain a view of the glottis or epiglottis, but the impaired state of the voice and its gradual abolition, and the painful difficulty of respiration, would indicate the excessive œdema of those organs In the cases seen the febrile reaction was not high, while the pulse usually varied from 100 to 120, and was usually feeble and compressible

Diagnosis.—Erysipelatous affection of the fauces, in my experience, never causes membranous exudations on the mucous surface attacked It can, therefore, always be easily distinguished from the diphtheritic form of disease Its wonderfully rapid development and progress, the excessive swelling and œdema, and invariable extension towards the larynx, at once distinguish the disease from amygdalitis From simple laryngitis it differs in the fact that erysipelas always begins in the structures of the pharynx—the tonsils, velum, uvula, and posterior portion of the tongue, and progresses downwards From simple glossitis, which is often very rapid, erysipelas of the throat differs in the presence of the enormous inflammation and swelling of the faucial structures peculiar to the latter affection, and entirely absent in the former

The increase of inflammation and swelling in erysipelas of the pharynx is more alarmingly rapid than in any disease of my acquaintance, and the loss of voice and difficulty of respiration are correspondingly great

The disease may be diagnosticated from scarlet fever by the appearance of the tongue, which is rather of a pale, livid appearance in the beginning, and ultimately becomes swollen and of a dark livid color, differing materially from the scarlet red "strawberry tongue" of scarlatina The sense of impending suffocation is, in the advanced stages, always sufficiently great to cause an infinite degree of mental and physical distress and suffering

Prognosis.—The prognosis of erysipelas of the throat is of the gravest character Without speedy and prompt relief a fatal termination will invariably

ensue The rate of mortality has not infrequently attained 90 per cent From 70 to 80 per cent is frequent

Treatment—Twenty nine years ago the first case of erysipelas of the pharynx and larynx came under my professional observation The history of the case may be summed up in the following brief statement The patient was a young man of 19 years, of good family, but having a hereditary disposition to tuber cle He was attacked in the night with what was supposed to be an ordinary tonsillitis But in the course of four hours the inflammation of the structures of the pharynx had become very great and the deglutition almost impossible, while the difficulty of breathing had become distressing The voice, even at this stage, showed indications that the vocal organs were beginning to participate in the trouble By 7 A M the patient was in extreme danger The voice, previously reduced to a mere whisper, was now entirely obliterated The respiration was stertorous, at times gurgling, and exceedingly labored and distressing The complexion was livid The interior of the pharynx, when the livid and swollen tongue was depressed, presented the appearance of a solid red mass, without anatomical outlines The enormously swollen tissues had encroached upon the openings of the posterior nares, throat and glottis to such an extent as to very nearly close them At this stage the patient was threatened with asphyxia, as the larynx had manifestly been involved by the erysipelatous disease, in addition to the obstructions existing in the posterior nares and pharynx The patient now suffered from extreme and painful difficulty of breathing and great restlessness The face and complexion of the hands became almost livid, the pulse frequent and feeble, the skin cool The swollen tonsils and palate were freely scarified, with the expectation that the local depletion might reduce the œdema and relieve the distress It failed to give any alleviation whatever Nitrate of silver was also liberally applied, but without benefit

The patient being now entirely unable to swallow, no internal treatment could be resorted to In consultation, as a *dernier ressort*, tracheotomy was proposed This was opposed obstinately by the friends of the patient Determined to give my patient another chance for life, and suspecting that this throat affection was erysipelatous in nature, from the fact of a prevailing tendency to that affection existing at the time, I decided in this case, as a mere experiment, to resort to extensive counter-irritation by some agent that was speedy, prompt, efficient, and at the same time harmless in character, hoping thereby to induce extensive dilatation of the cutaneous capillaries and a transference by metastasis of the erysipelatous action to the surface The sinapism was selected as the counter-irritant to be used in this case The entire neck, front of the chest, and back, corresponding to the scapulæ and upper part of the spine, were speedily covered or enveloped in strong, freshly prepared sinapisms In ten or fifteen minutes the sinapisms began to act In thirty minutes the burning pain over the entire surface enveloped became almost intolerable Then, for the first time, the patient began to experience some relief to the obstructed respiration Increased relief was now experienced every minute, and corresponding improvement of respiration On removal of the sinapisms, it was found that the entire surface of the neck, front of the chest, and upper dorsal region, was covered with a universal deep red blush The relief to the respiration was now such as to enable the patient to inhale sufficient air to sustain life for the time Equally remarkable and pleasing were the local changes in the fauces There was a manifest subsidence of inflammatory action and œdema of the structures involved Within a few hours a very extensive attack of erysipelas had been developed over the chest and a portion of the lower neck

The effects of this development upon the disease of the pharynx and larynx, and tongue, was truly marvellous The internal affection had almost completely subsided, the difficult respiration was relieved, the internal affection transferred by metastasis to the external surface, and the life of the patient saved

This peculiar feature of this case serves to illustrate in a remarkable manner that inherent characteristic of erysipelas to change its location, by metastasis, from one organ to another This very interesting fact also furnishes an intimation of value in our treatment of the disease when attacking vital or important internal organs, that relief may be attained by encouraging this tendency by means of counter-irritation Prompt, speedy, effectual counter irritation by means of sinapisms extensively used, was found to act most favorably in every respect Such counter-irritants as epispastics, ammonia, oil of turpentine, are inadmissible, because they may establish inflammatory action sufficiently violent in type as to cause gangrene of the skin

I regard it as exceedingly fortunate in this case that tracheotomy was not resorted to If such had been the case, then erysipelatous inflammation would surely have attacked the tracheal wound Tracheotomy is manifestly an operation not suitable to erysipelas of the fauces Since the successful treatment of this case by means of counter-irritation, I have resorted to the remedy not only in all cases of the genuine disease, but also in all cases presenting indications of an erysipelatous tendency involving the faucial surface, and always with benefit In true cases of this kind, the remedy will always bring out a crop of erysipelas on the surface Prompt and extensive counter-irritation by means of sinapisms applied thoroughly around the neck, over the chest and back, covering the scapulæ, was found by myself and three medical friends to whom the practice was suggested, so as to produce dilatation of the cutaneous capillaries on a widespread scale, and thereby inviting the flow of a large amount of arterial blood from the internal structures to the surface, to act manifestly as an important diversion of the circulation, and form a positive diverticulum which invariably, according to our experience, afforded speedy relief to internal disease, and saved life A medical friend in a distant section of this State, which was infected with erysipelas of the fauces of an exceedingly malignant type, who, on my suggestion, applied this

simple method of treatment to his patients, informed me that the most favorable results followed, in almost every case, after its application, whereas previously the results, under other treatment, were almost invariably fatal

In certain cases which have come under my observation during the prevalence of erysipelas having many of the characteristics of erysipelas, but wanting in others, I have also found this thorough method of counter-irritation to act exceedingly favorably in relieving the enormous congestion and inflammation of the faucial structure While in this class of cases there was no appearance of erysipelas on the surface following the counter irritation, the irritation of the skin being very extensive afforded relief to internal trouble In these cases of metastasis of erysipelas from the fauces to the skin, caused by the action of the counter irritant, all local means of treatment should be desisted from, because of the known tendency to migrate The tincture of the chloride of iron, hydrochloric acid, chlorate of potash, and the liquor arsen chloridi may be used advantageously internally

Case 2 —An adult, aged 40, was attacked with an affection of the throat, supposed to be acute tonsilitis, but what in a few hours proved to be a dangerous attack of erysipelas of the pharynx and larynx The œdema and inflammation of the faucial structures became enormous, so as in a few hours to endanger respiration The breathing became first of a snoring character, then stridulous, finally muffled, and almost indistinct, because of the great obstruction At this stage the tone of the respiratory murmur throughout the chest also became exceedingly feeble, indicating a deficiency of inhaled air The tongue and skin assumed at this stage of the case a decidedly livid appearance The pulse was feeble and frequent, and the extremities rather cool In this case the same system of extensive counter-irritation was resorted to as in the former, and with equally favorable results

In erysipelatous affections attended with great rise of temperature, with delirium and a tendency to cerebral complications, I have for some time past used salicylate of soda, and more recently with still better effects, the salicylate of ammonia While my experience in the use of this remedy is not extensive, it is sufficiently so to establish in my estimation its merits as a valuable agent in the treatment of this peculiar type of the disease

Cerebral complications of erysipelas are usually regarded as examples of metastasis to the brain I regard this view of the case as questionable In those cases of cutaneous erysipelas involving the brain, there is certainly no subsidence or disappearance of the external affection, while the internal affection may continue to increase in gravity All cases of this kind seen by me, I have had good reason to regard as true examples of embolism of some of the cerebral vessels, occurring first at a circumscribed spot, or locality, the effects of this gradually radiating in the form of engorgement and inflammation, and ultimately producing an area of morbid action, often of an extended character, which may terminate in softening or suppuration I am not aware that any treatment heretofore instituted has been able to reach this class of cases, certainly the authors have given us none In the past few years, in a few cases threatening cerebral complications in which I had reason to suspect a tendency to embolism, I have prescribed with decided benefit the salicylate of ammonia in gr xx doses every three hours, and the mistura ferri et ammon acetatis in ℥ss doses in connection with it, also every three hours This is a far better treatment in this class of cases than the traditional tinct of chloride of iron and quinine The therapeutic action of the salicylate of ammonia is eminently antiseptic, acting specifically on the septic form of inflammation, and when combined with the carbonate of ammonia, I believe it promises more for the dissolution and removal of emboli than any other agent It has proven to be, in my hands, an efficient antipyretic

In conclusion, I can say truthfully, that in the treatment of erysipelas of throat, time is a precious and vital consideration Local applications of iodine, nitrate of silver or simple astringents, are worse than useless, they are deceptive The internal administration of quinine and iron is impotent for good We want some agent which will produce promptly and efficiently an extensive counter irritation, and sudden dilatation of the cutaneous capillaries over the seat of the internal erysipelatous affection, thereby relieving the enormously engorged structures and preventing closure of the glottis In certain cases, accompanied with excessive œdema of the cellular tissue of the neck and adenitis, I have found the flaxseed poultice thoroughly covered with mustard, applied very hot and frequently renewed, to exert an admirable influence in reducing the adenitis and œdema

---

ANTIPYRIN IN RHEUMATISM, ITS VALUE AND MODE OF ACTION

BY N S DAVIS, JR, A M, M D,

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE CHICAGO MEDICAL COLLEGE

Read before the Section of Practice of Medicine, Materia Medica and Physiology, at the Thirty Eighth Annual Meeting of the American Medical Association, June 8, 1887

During the last few months numerous writers in Germany and France have described the good effects of antipyrin in acute rheumatism It has been said of it that it relieves the pain and allays the fever as quickly as does the salicylate of soda, and that under its influence the cutaneous redness over the affected joints, and their swelling, gradually but soon disappears

All of these statements I can confirm by my experience during the last four months in some twenty cases

I have used antipyrin in acute cases, also in those that were subacute and in the acute exacerbations of those that were chronic I noticed early that the greatest and most rapid improvement was obtained in cases in which there was a rise of temperature above the normal

The first case in which I used antipyrin was one of chronic rheumatism in which there was, at the time, an acute exacerbation The patient's stomach was so irritable that very little was retained by it Enough of salicylic acid or of the salicylates could not be given to produce an impression on the disease I therefore tried as an experiment a single dose of antipyrin, of twenty grains, at bed time Soon after taking the medicine the pains, which were uniformly much more severe at night than during the day, were eased The patient breaking into a profuse perspiration, fell asleep and passed the first restful night for some weeks After a few days under this treatment her fever disappeared and she was almost free from pain When the fever was wholly wanting it was noticed that the antipyrin ceased to ease the pain that remained, and did not relieve the chronic stiffness and swelling of the joints As often, however, as the temperature rose the antipyrin acted well I have met with similar results in the treatment of three other cases of chronic rheumatism No relief to the pain, swelling and other symptoms of inflammation was obtained in a case of gonorrhœal rheumatism in which one ankle, one knee and the joints of the fingers were much swollen and exceedingly painful There was in this case at the time no fever.

As an illustration of the action of antipyrin in acute cases, I will cite the history of a young man recently dismissed from Mercy Hospital, apparently cured He had been sick with a sharply acute and quite severe attack of rheumatism for ten days, when he entered the hospital During that time most of the large joints had been in turn affected When first seen by me his temperature was 103°, his pulse quick, bounding, full, but compressible, his skin moist, with moderate perspiration, his countenance indicated pain and distress At the time the pain was almost wholly limited to the left knee and right shoulder and elbow All these joints were considably swollen, and the skin over the knee was very slightly reddened There were no evidences of endo- or pericarditis Appetite was completely wanting, but thirst was much increased The bowels were constipated The urine was somewhat scant and highly colored Sleep of more than momentary duration had been impossible for many days In a word, the patient at the moment presented the symptoms characteristic of a typical case of acute rheumatism As it was one of the earliest cases of acute rheumatism that I treated wholly with antipyrin, I ordered at first the administration of a powder containing twenty grains of the drug only night and morning The following afternoon he reported that soon after taking the medicine he slept, and for three or four hours was free from pain, but as the influence of the drug wore off the pain returned His temperature had then lowered, but was still considerably above normal I now ordered the antipyrin powders given three times daily instead of twice Two days later the patient looked much better, and described himself as almost free from pain, the cutaneous redness over the knee was gone, and all the joints were less swollen, but still stiff and somewhat painful on attempted motion The temperature for the most part during the preceding twenty four hours was normal, twice it rose slightly The frequency of the administration of the antipyrin was left to the judgment of the house physician, the directions being to administer the drug whenever the temperature rose or an access of pain occurred Following this plan, he received during the next two days two powders daily He was entirely comfortable so long as quick and violent movements were not attempted For eighteen hours there had been no abnormal temperature The swelling of the joints was much less, and freedom of motion much greater The case progressed steadily in a favorable manner, and all stiffness and pain disappeared during the next week The antipyrin was continued for several days after all fever was gone No other medicine was administered after its discontinuance, the patient simply being guarded against adverse atmospheric influences

In the other acute cases in which I have tried antipyrin I have been most pleased with the readiness with which it relieved pain and lessened fever In some instances the improvement was more marked and more rapid than in the case I have just sketched, in others it was somewhat slower, but always decided I feel confident that, so far as a limited number of cases will permit one to determine, antipyrin can be said to be as efficacious as the salicylates Being at first impressed with the thought that the relief obtained in rheumatism was due to the antipyretic effects of the drug, I substituted for it salicylic acid as soon as the temperature became normal, as, however, experience showed that the efficacy of antipyrin did not depend upon this property, I continued its use, as improvement took place, in lessened doses and less frequently until a cure was established

In the hospital cases most recently treated the drug has been used in fifteen grain or gram doses, administered at the height of the disease every four hours, diminishing the frequency of its repetition as improvement occurred It has seemed to me that I obtained more satisfactory results in my private patients to whom I gave it in larger, twenty grain, doses, four times daily, when the disease was at its height, and to whom, during the period of improvement, it was given in smaller doses, but not at first less frequently From sixty to ninety grains (four to six grams) daily are recommended usually by those who have employed antipyrin in rheumatism

The advantage of antipyrin over the salicylates consists chiefly in its less nauseating properties, its less liability to provoke vomiting, headache, and noises in the ears Not unfrequently a patient is found who can not take the salicylates in efficient doses While trying antipyrin, both in rheumatism and in other febrile diseases, I have found only one or two persons who rejected it, and a few others, whose stomachs were irritable, who complained of slight nausea immediately after taking it These effects are, however, much less frequently produced by it than by the salicylates It can also be given efficiently, when necessary, by the rectum or subcutaneously

The only ill effect that is likely to result from the

use of antipyrin is the so called "antipyrin rash" This is seen only in a very small proportion of the cases treated with it Two or three cases of fatal collapse have been reported, occurring in typhoid patients after taking antipyrin At the most, however, this is an exceedingly rare accident, and it is questionable even if, in the cases referred to, the accident was due to the antipyrin Ringing in the ears has been reported as occurring, but so seldom that it need not be looked for when the usual doses are used

Others have found, very rarely, a case of acute rheumatism in which no relief could be obtained from the antipyrin treatment The same can be said, however, of the usual salicylate treatment

The use of the drug does not appear to influence the frequency of the occurrence of heart complications, and their existence is not a contra indication to its employment

It is impossible, from what we yet know of the nature of rheumatism and of the physiological action of antipyrin to explain thoroughly its therapeutic action The perspiration which very uniformly follow its administration, and in rheumatism seems to accompany the diminution of pain, is probably due to relaxation of the cutaneous vessels, such as has been observed by Beyer[1] and others, and which naturally would feed and stimulate the cutaneous glands It has been shown that the peripheral vessels dilate under the influence of antipyrin, the arteries dilating when large doses are administered, and only the veins and capillaries when smaller ones are employed Whether this change of calibre is due to vaso motor influence or not is undecided, some claiming that the change is brought about by the direct action of the drug upon the vessels, since similar changes take place in isolated organs," others claiming the reverse to be true [2]

Antipyrin, when mixed with blood, does not cause a change of color or destruction of the corpuscles, as does kairin, thallin, resorcin,[3] and probably antifebrin [4]

Possibly its antipyretic properties are to be explained by the vascular changes which it produces, since they would contribute to increase the radiation of bodily heat This is the explanation offered by Bettelheim,[5] Auseroff and Beyer Arduin thinks the diminution in temperature is due to an influence exerted upon the thermogenic nerve centres During the last month P J Martin[7] has published the results of experiments which show that, almost uniformly, heat production is diminished by antipyrin, and heat dissipation is very much increased It thus would seem to be an ideal antipyretic In the small proportion of cases in which heat production was not diminished, heat dissipation was so far in excess that the bodily temperature was lowered Several observers have noted that under the influence of antipyrin the surface temperature rises while the internal temperature of the body falls [8]

Its power of allaying pain in rheumatism is probably not dependent upon these vascular changes or the apyrexia produced by it, but upon a direct action on the nervous structures of the body Antipyrin, though apparently most efficacious in rheumatic fever and least in muscular rheumatism, still, even in the latter, often acts beneficially In many painful disorders purely neuralgic in character it gives the most prompt relief, for example, to the sharp neuralgic pains of locomotor ataxia Ungar,[9] T S Robertson,[10] and others, say it is efficacious in migraine Germain Sée[11] has witnessed its power of relieving pain in other forms of neuralgia, and in gout, lumbago and sciatica

The fact that there was in these diseases no common pathological effect except that of pain, led the last writer to study particularly its action upon the nervous system The results of his experiments he reported to the French Academy of Sciences on the 18th of April of this year When injected subcutaneously in dogs three kinds of phenomena were observed In the first place, a notable diminution of sensibility was observed, a true analgesia of the limb injected, sometimes, also, of the opposite one. In the second place, electric excitation of the sciatic nerve produced in the muscles of the opposite side only very feeble contractions, which points to diminished sensibility and reflex power in the spinal cord In the third place, when antipyrin was introduced into the circulation of an animal except into one limb, the vessels of which were ligated, it was found that throughout the body the muscles contracted slowly and with difficulty, while those of the ligated limb contracted with their wonted vigor It is evident, therefore, that antipyrin also affects the muscles, or more properly, perhaps, the nerve endings in the muscles Analgesic effects have been frequently noted by others Large doses administered to animals cause convulsions, both clonic and tonic Lessening of the reflexes, also, has been observed by others, as, for instance, by Arduin [1] This last author, as well as Coppola,[13] thinks that the brain is influenced by the drug, since, when convulsions are produced by it, their severity is much diminished if the brain is separated from the cord

Antipyrin does not affect the respiratory movements, although the frequency of respiration in fever diminishes as the temperature falls under its influence As ordinarily administered, the rhythm and strength of the heart's action are not influenced Beyer has shown by physiological experiments that when it exists in small amounts in the circulatory fluids it causes an increase of work performed by the heart, while in large doses the contrary effect is produced

Some have also noted increased force in the heart's action, while others have observed a diminution in it This discrepancy is probably due to the size of the dose administered

The drug is eliminated by the urine, and can be found in it two hours after administration, and usually for thirty six to forty eight hours afterwards [14]

The following conclusions are, I think, justified by our present knowledge of antipyrin in the treatment of rheumatism 1 It is as efficacious as the salicylate of soda, producing similar therapeutic results, and is less nauseous than the latter, and does not produce headache or ringing of the ears 2 Usually it acts most efficiently in the most frankly acute cases 3 Besides reducing, by its antipyretic properties, the fever, and also the pain, which many antipyretics relieve, it reduces the pain by acting directly upon the nervous system

MEDICAL PROGRESS.

COCAINE IN LABOR AND GYNECOLOGY —DR GEO H ROQUE DABBS, in a note on this subject, tabulates his observations as follows

1 I obtained equally good results from a 6 per cent solution as from a 12 per cent solution of cocaine (hydro chlorate), but in dry labors I now use a ¼ per cent solution of the alkaloid itself in castor-oil Into the thin parchment like os I put a cocaine saturated plug of cotton wool, which I renew (or rather replace with a fresh plug) about every half hour, until fair dilatation has taken place

2 In cases in which the labor progressed so slowly that some assistance is needed, and yet the cocaine need not as yet, be deposed in favor of chloroform, the form in which I have found ergot of most benefit has been as a hypodermic combination of sclerotic acid, gr ⅙, and bimeconate of morphine, gr ⅓ By means of Burroughs's tabloids I have been thus able to secure a certain degree more of uterine action, and with the bimeconate of morphine combined with the sclerotic acid and the internal application of the cocaine, have now seen many cases of almost absolutely painless dilatation of the os

3 But of all uses for cocaine in connection with first labors, I have obtained the most gratifying results from the application of a 12 per cent solution to the vulva and inside of the vagina during the slow progress of a case of marked perineal rigidity I do not, of course, mean that the case is hastened much but I do mean that the pain is lessened to an extraordinary degree

4 My observations lead me to conclude that it is chiefly in primiparous (slow) labors that cocaine is of use (notably in breech cases), or in any case possibly in which the os dilates slowly and the perineal rigidity is well marked

5 In cases in which the os has to be dilated by tents, I have soaked and partly enlarged the tents in a hot oleaginous solution of the alkaloid before introducing them, with, as I think, considerable success, and in cases of tender and irritable vaginæ in which, for any reason, the speculum has to be used (gynecological cases), I have adopted the practice with great advantage of previously painting the vaginal walls with the solution of cocaine in castor oil before alluded to —*British Medical Journal*, April 30, 1887

OSMIC ACID IN SCIATICA —NEUHER first suggested osmic acid as an anti neuralgic remedy, and published the results of three cases, two of sciatic neuralgia, and one of the facial From ten to twenty-five injections were required to effect a cure *Eulenberg obtained three radical cures and four* ameliorations out of twelve cases Many others have used it with very much the same results, *i e*, with benefit in some cases, and without benefit in others Dr Stékoulis has tried it in twelve cases (six men and four women) of idiopathic sciatica, the duration of which varied from fifteen days to two years The result of the treatment was eight successes, one much improved, and one in which the remedy proved inert, after four injections, beyond which the patient refused to go Its effect is explained by the well known effect of osmic acid on certain constitutents of nerve tissue *No abscesses nor other* inconvenience followed its use beyond the pain at the time of the injection An aqueous solution, containing 1 per cent of acid, is generally used, of which about sixteen minims are injected It stains the skin and clothes black The injection should be made *loco dolenti*, at first daily, and then less frequently —*London Medical Record*, May 16, 1887

PUNCTURE AND INJECTION OF ETHER AND IODOFORM IN PURULENT ABSCESS OF THE BUTTOCKS —At a recent meeting of the Paris Surgical Society, M TRELAT reported a case of purulent abscess, successfully treated by puncture and injection of ether and iodoform The patient, a girl aged 17, had been attacked with typhoid fever eighteen months previously, and the abscess was diagnosed as necrobiotic, consecutive to vitreous alternation of the muscular fibres A puncture was made, which gave issue to 45 grammes of pus, and 90 grammes of ether and iodoform were injected into the cavity M Trélat asked whether simple abscesses might not be treated in the same way M Terrier thought that in cases like that cited by M Trélat simple puncture was sufficient M Championnière has found iodoform very irregular in its effects, and objected that the injection of this substance in ether constituted a long and painful treatment M Dentu had obtained better results with alcohol and chloride of zinc M Trélat, in his reply to these objections, *stated that it was important* in an æsthetic point of view, to avoid the cicatrix which always remained after an incision, and this was practically accomplished by puncture and the injection of iodoform —*London Medical Record*, May 16, 1887

THE ILLINOIS PRACTICE ACT

On June 15th the Illinois Legislature passed a bill for an amended medical practice act Though the wording is different in almost every section, the bill as passed is very similar to the original practice act, passed in *1877* *The chief difference is to be* found in Section 10 of the new act, which reads as follows

Any person shall be regarded as practicing medicine, within the meaning of this act, who shall treat, operate upon, or prescribe for any physical ailment of another But nothing in this act shall be construed to prohibit service in cases of emergency, or the domestic administration of family remedies

As before, this section is inapplicable to surgeons of the Army, Navy, and Marine Hospital services The other amendments to the old practice act are, the doing away with the "ten years' practice" clause, fixing a fee of $20 for the examination of non graduates (which fee is returned if the applicant fail to pass the examination), and giving the State Board of Health power to license itinerant vendors (the fee being $100 a month)

In connection with this subject may be mentioned the case of George J Williams *vs* The people of the State of Illinois, error to Criminal Court, Cook Co , recently decided by the Supreme Court, opinion delivered by Judge Sheldon, and the judgment of the lower court affirmed Under the practice act of 1877, Williams was fined $200 for practicing medicine illegally It was held by the attorneys of the plaintiff in error that the act under which the conviction was had is unconstitutional Judge Sheldon said "We do not understand the act to be challenged in this respect in the regard of its feature of prescribing qualifications for the practice of medicine It is the common exercise of legislative power to prescribe regulations for securing the admission of qualified persons to professions and callings demanding special skill And nowhere is this undoubtedly valid exercise of the police power of the State more wise and salutary, and more imperiously called for, than in the case of the practice of medicine It concerns the preservation of the health and lives of the people But the constitutional objection which is urged against the act is that it is special legislation The special feature which is claimed is the proviso to the act, which is, 'Provided, that the provisions of this act shall not apply to those that have been practicing medicine ten years within this State This proviso does not confer upon the ten years' practitioners any special privilege, immunity or franchise It does not confer upon them anything, it leaves them as they are

"But it is said the act is one to regulate the practice of medicine, and that it subjects to regulation only a class, to wit graduates with diplomas and applicants for a certificate of examination, while the ten years' practitioners are not subjected to any regulation at all, by anything in the act It becomes proper to look and see what the provisions are The first clause of the act is as follows 'Every person practicing medicine in any of its departments, shall possess the qualifications required by this act' All the other provisions of the act as we view them, only *respect such qualifications, with the exception of one* section, which requires any itinerant vender of any drug or nostrum, ointment, etc , to pay a license of $100 a month It was within the province of the legislature to prescribe what should be the qualifications for the practice of medicine, and what the mode in which they should be determined The act provides as to a graduate in medicine with a diploma, that he may practice upon his diploma, it being verified as pointed out by the act In regard to others, it is provided they shall undergo an examination before the State Board, or Board of Examiners, and may practice upon the certificate of the Board As *respects the proviso, we regard it in the light of but* prescribing a qualification, that ten years' practice within the State should constitute a qualification for practicing medicine

"It is virtually conceded in the argument of appellant's counsel, that the general assembly might make the qualification of ten years' practice prior to the act, equal to the qualification of a diploma or certificate of examination, and that the proviso might have been un-

objectionable had it been limited to the provisions of the act in respect of qualification—that its vice is in saying, that 'the provisions of this act,' that is, that not its provisions in respect of qualifications, but each and every of its provisions should not apply to the ten years' practitioners And it is said that there is one section which regulates practitioners in respect to conduct, giving the power to exclude them from practice for unprofessional or dishonorable conduct, and that this is a provision from which the ten years practitioners are, by the proviso, exempted This section referred to is that the Board may refuse certificates to individuals guilty of unprofessional or dishonorable conduct, or may revoke certificate for like causes

"As respects the objection of this provision unjustly discriminating between classes of practitioners, we regard it but as a regulation pertaining to qualifications for admission to practice It certainly is such, as regards applicants for admission, and as respects those who had been admitted to practice on the Board's certificate, the provision essentially is that where there has been abuse of the license granted, by having been guilty of unprofessional or dishonorable conduct, the licensing Board may revoke the license which they had granted All is really but in regulation of admission to practice upon the certificate of the Board It has no application to ten years' practitioners, as they are not admitted to practice upon the Board's certificate, but they are, by the act itself, licensed to practice The propriety of the provision as regards the holders of certificates, in making their certificates subject to revocation by the Board for unprofessional and dishonorable conduct, we do not regard as involved in this case, or that we are called upon to express any opinion thereon Appellant has no grievance in this respect He has not had any certificate revoked, has never received a certificate, or been licensed to practice And if, in this particular, the act could be regarded as unconstitutional, we would not hold the entire act, for that reason, to be void, or to be so, in so far as it bears upon the appellant

"It is assigned for error that there is no evidence in the record tending to show that appellant had not complied with the requirements of the law, and had not practiced medicine ten years previous to 1877, and in refusing to instruct the jury that the burden was on the prosecution to make such proof

"The case comes within the general rule upon this subject which is laid down by Greenleaf 'But where the subject matter of a negative averment lies *peculiarly within the knowledge* of the other party, the averment is taken as true, unless disproved by that party Such is the case in civil or criminal prosecutions for a penalty for doing an act which the statutes do not permit to be done by any persons, except those who are duly licensed therefor, as, for selling liquors, exercising a trade or profession, and the like'" Judgment was affirmed

THE JOURNAL

The present number of THE JOURNAL commences the fifth year of its publication and the ninth volume And, what is of more importance, it contains a material increase in the number of its pages, and other marks of improvement, justified by the increased income of the Association during the past year The same circumstances that have justified the addition of more pages of reading matter have also enabled us to make reliable arrangements for additional work in all departments of journalism The first sixteen or eighteen pages of each number of this volume will be occupied mostly by the addresses and papers presented at the recent meeting of the Association, not, however, to the entire exclusion of valuable papers from other sources, but we shall endeavor to secure more attention to selection of the more valuable items in the proceedings of active Medical Societies in all parts of our country, more prompt, though brief, notices of new books, greater variety in the leading or editorial articles, and careful noting of important sanity measures and of attempts to regulate medical education and practice by legal enactments

In the last number of Volume VIII, June 25, we gave the full record of proceedings of the thirty-eighth annual meeting of the American Medical Association, including two or three reports containing matters of more than usual interest, and which we hope will attract the attention of every reader To some of these we shall have occasion to refer more at length before the time to commence arrangements for the next annual meeting

WASHING OUT THE STOMACH

In an article in *L'Avenir Medical*, DR LEFRANC condemns the indiscriminate use of the tube so much in fashion at the present time for washing out the stomach and for feeding in certain cases, as the frequent introduction of any instrument into the stomach, however pliable or inoffensive it may appear, must after a time prove injurious to that organ

Washing out the stomach has been practised in two principal forms of dyspepsia the putrid, and in

that form known as dilatation of the stomach In the first case, the object is to remove the putrid and fermented matters lodged in the stomach In the second, the object is to promote the contractility of that organ, the effect of which is supposed to be analogous to that produced by a douche on the striated fibres of the voluntary muscles But, besides the analogy not being quite applicable to the smooth fibres of the stomach, the results predicted by those who have been instrumental in introducing this mode of treatment into practice have not been confirmed by clinical experience Dr Lefranc suggests that when it is proposed to determine on the stomach of a dyspeptic a profound and durable curative action, it should be remembered that the gastric mucous membrane is in such cases in a permanent state of catarrh, more or less intense, and that it is loaded with ferments But the stomach itself possesses a fermenticide much more efficacious than washing it out, an operation which, as has been already observed, is far from being inoffensive, and is sometimes followed by the most disastrous results, and even by death this is the physiological gastric juice in sufficient quantity The best means by which to combat or prevent the formation of ferments in digestive trouble is by adopting the neurasthenic medication which acts directly on the stomach, of which the spasms and nervous gastric symptoms are calmed, and the glandular function of the organ is stimulated or rectified To fulfil these indications the bitter tonics, such as calumba, nux vomica and quassia, are the most effectual remedies

HYDROCHLORIC ACID SOLUTION IN DYSPEPSIA — In connection with the treatment of affections of the stomach, we may note that DR TALMA asserts that he has employed with advantage, hydrochloric acid in the proportion of 1 gramme to 750 grammes of water This is the strength for adults, and the solution should be made lukewarm, and taken in small quantities in the twenty-four hours The best effects are produced, particularly when the remedy is taken after each meal The diet should be attended to fat should be excluded, and contrary to precedent Talma does not prescribe milk for chronic catarrh nor for ulcer or cancer of the stomach Hydrochloric acid not only prevents the fermentation of the contents of the stomach, but by its antiseptic action it has also a beneficial influence on the coats of that organ In nervous patients, or those showing a peculiar susceptibility to the action of hydrochloric acid, Dr Talma begins by employing alkalies before administering the acid In another series of cases, in which despepsia was caused by cerebral anæmia, as in pregnant women, Dr Talma has obtained good results by the employment of nitro glycerine in doses of 1 milligramme in the twenty four hours But before Talma, Trousseau had long ago prescribed hydrochloric acid in the treatment of dyspepsia, and many specialities of the present day, owe their success in diseases of the stomach to the presence of this acid

FUNDS FOR THE NINTH INTERNATIONAL MEDICAL CONGRESS

At the recent meeting of the Executive Committee of the Congress, it was directed that all receipts from membership fees be reserved for the publication of the transactions, and the $10,000 appropriated by Congress, with so much of the moneys donated by individuals, medical societies, etc , as may be necessary, may be used for preliminary printing and for the accommodation and entertainment of the Congress At a recent meeting of the Illinois State Medical Society an appropriation of $750 was made, at the meeting of the American Medical Association, $1,000, at the meeting of the Kentucky State Society, $250, and the Faculty of the Medico Chirurgical College, of Philadelphia, contributed $100 These contributions added to those previously reported, give assurance that the financial interests of the Congress will be well sustained

THE BUREAU OF GENERAL INFORMATION, WASHINGTON, D C —Physicians and others who desire to obtain information and references from the library of the Surgeon General's office, or from any other sources in Washington, will find it to their advantage to communicate with the Manager of this Bureau, Joseph B Marvin, P O Lock Box 379, Washington, D C

SOCIETY PROCEEDINGS

ASSOCIATION OF AMERICAN PHYSICIANS

Second Annual Meeting, held in the Army Medical Museum Building, Washington, June 2 and 3, 1887

THURSDAY, JUNE 2—FIRST DAY

The meeting was called to order by the President, DR S WEIR MITCHELL, of Philadelphia, who delivered a brief address in which he referred to the purposes of the Association He reported the death of three members, Dr Thomas F Rochester, of Buffalo, Dr Thomas A McBride, of New York, and Dr E Darwin Hudson, Jr , of New York

DR R PALMER HOWARD, of Montreal, read a paper on

CIRRHOSIS OF THE LIVER IN CHILDREN

He reported two cases in which cirrhosis of the liver was present in children, brother and sister He exhibited sections of the organ

DR WM A WEICH described a case of cirrhosis in a child twelve years of age He came from the coast of Africa and suffered with malaria Both the liver and spleen were deeply pigmented The clinical features of the case could not be obtained Most of the cases of cirrhosis of the liver of malarial origin have been reported from the coast of Africa

DR F FORSHEIMER, of Cincinnati, had seen two cases that may possibly be called cirrhosis One was that of a child of eight years At the autopsy the characteristic hob-nail liver was found In this case he considered the cirrhosis due to syphilis The second case is now under observation, the patient being in the last stage of cirrhosis In this case there is a history of syphilis and the child has hereditary syphilis of the nervous system To his mind it is clear that syphilis is the most common cause of cirrhosis of the liver in children

DR WILLIAM PEPPER, of Philadelphia, reported a case in which cirrhosis of the liver followed measles in a child eight years of age During the attack of measles, there were symptoms of hepatic disorder as shown by occasional attacks of catarrhal jaundice Subsequently the symptoms of developing cirrhosis made their appearance and death in a comatose condition finally occurred The whole duration of the case could not have been less than a year At the autopsy a typical hop-nail liver was found

DR JOHN GUITERAS, of Charleston, S C, read a paper entitled

OBSTRUCTIVE SAFETY-VALVE ACTION IN THE HEART, AND DIRECT FUNCTIONAL MURMURS

In a previous paper on malignant endocarditis the author had dwelt upon the significance of mitral direct presystolic murmurs, which were proven by the autopsy to be unconnected with any lesion of the mitral orifice The lesions were those of intense aortic regurgitation He had attributed the murmurs to the recoil of the blood upon the mitral leaflets holding them tense against the stream of blood coming from the auricle In the opinion of the late Dr Flint, direct functional mitral murmurs were limited to a small number of cases of aortic regurgitation, but the author thought that the functional mitral murmurs were not so rare Obstructive functional murmurs are common in aortic regurgitation

Pulmonary systolic murmurs are more frequent than any other form of cardiac murmurs In examining one hundred consecutive cases, he had found in sixty-two, systolic, pulmonary artery murmurs In these the murmurs were present during tranquil breathing or during respiration in such a way as to produce changes in the pulmonary circulation If account is taken of the bruits heard in this region the proportion becomes greater The clearness with which these murmurs are heard depends upon the proximity of the artery, the thinness of the chest walls, the nature of the surroundings, and finally the proximity of the main trunk to the capillary distribution Systolic pulmonary murmurs can be developed in the majority of healthy individuals, if we exclude those with thick chest walls and those who are not intelligent enough to modify their breathing as directed The author held that such a murmur was a dynamic, obstructive valvular murmur, and is produced by the effect of changes of blood pressure upon the semilunar valves A certain degree of pressure in the artery must tend to prevent the opening of the valve This causes a slanting position of the valves, and a narrowing of the orifice, with the production of a sonorous whirl The fact that such murmurs are not more frequently developed at the aortic orifice is due to the greater power of the ventricle and the wider distribution of the systemic circulation There are, however, cases in which increased arterial tension is expressed not only by accentuation of the aortic second sound, but by an aortic systolic murmur He had heard it in atheroma, and in Bright's disease, where there was no marked anaemia Pulmonary artery murmurs as heard in ordinary breathing is confined to the expiratory act and is broadest at the beginning of the act The murmur is sometimes only heard with the first beat that occurs with expiration In order to further develop this murmur, it is only necessary to arrest respiration It is better to stop breathing during expiration, especially at the end of normal expiration A full expiration makes the murmur louder At the end of inspiration, it is more difficult to develop the murmur, for several reasons 1 because it requires entire arrest of respiration to produce engorgement of the main trunk, 2 because prolonged inspiratory effort is accompanied by a continued hum of the intercostal muscles, 3 because the expansion of the lung interferes with the transmission of any murmur that may be present A slight murmur is frequently heard in inspiration if the arrest of breathing is pushed fast enough The speaker asked, are we not justified in assuming that there is a safety valve action in this attitude of the pulmonary valve, which together with the leakage at the tricuspid orifice, tends to prevent engorgement of the lungs by the retardation of the flow of blood in the systemic veins, so that continued for a time it does no harm? In reference to the murmurs of anæmia, the author thought that they were due to some disturbance of the apparatus In this condition there is a marked reduction in the quantity of blood, the valves require a certain amount of expansion of the vessels in order to allow them to apply themselves to the walls Venous hums and basic murmurs he thought to be of valvular origin

DR A L LOOMIS, of New York, remarked that we should recognize that murmurs within the heart cavities are due to many different causes The obstructive mitral murmur referred to, were, he thought, of frequent occurrence in connection with aortic diseases where there is dilatation and feebleness of heart power, but on autopsy he had always found such changes in the mitral valves as seemed to account satisfactorily for the murmurs heard He had

heard the murmurs so readily produced during respiration, but where these murmurs have been persistent, he had always found conditions of anæmia and failure of the right heart It seemed to him that the explanation is either hæmic or failure of heart power We shall as we study the cases more, find that they are due not so much to changes in the valvular orifices as to changes in the heart cavity, and in the heart walls Murmurs have come to be of very little pathological significance to him unless there are other changes associated with them The worst cases of heart disease he had met with have had the simplest and least distinct heart murmurs

Dr L T Bruen, of Philadelphia, reported a case of severe anæmia in which there was great relaxation of the muscular system, so much so that as the arm hung out of the bed, there was a venous pulse at the back of the wrist This was attributed to relaxation of the capillary vessels to such an extent as to permit the systolic impulse of the left ventricle to force the blood through the capillaries into the veins In this case there were murmurs at each of the valves of the heart As the anæmia improved and the crasis of the blood was restored, the venous pulse disappeared and the murmurs gradually lessened and the man has now no murmur whatever

Dr F P Kinnicutt, of New York, said that it has been claimed by certain observers that pulmonary systolic murmurs are transmitted from the mitral valve into the auricular appendage The condition required that this may occur is said to be dilatation of the appendage causing it to approach the chest wall In some anatomical examinations made a few years ago he found that in the normal condition the auricular appendage was concealed beneath the pulmonary artery, and when fully dilated its tip only could be seen beyond the edge of the artery It was even then one and a half inches from the internal surface of the chest

Dr F C Shattuck, of Boston, remarked that when auscultation was first introduced all cardiac murmurs were considered of bad omen It was then discovered that many systolic murmurs were practically *of no importance* We are now finding out that all diastolic murmurs are not of evil import and that they may be transitory and functional A murmur by itself is next to nothing, there must be something beside the murmur to make it of much importance

Dr Samuel C Chew, of Baltimore, said with reference to the diagnosis between aortic regurgitant and mitral direct murmurs, that the diagnosis can usually be made by attention to the following points An aortic diastolic murmur although it may be intense at the apex, becomes manifestly louder as we reach the right side of the sternum in the second intercostal space It will then occupy the whole diastole If the murmur is mitral in origin it generally will be also heard in the scapular region The aortic murmur is not apt to be heard in the latter situation

Dr Beverly Robinson, of New York, had occasionally found in acute strain of the heart, murmurs which unquestionably had nothing to do with organic changes in the heart, and can not be explained as due to any special modification in the blood The murmurs seem to be due to more or less acute dilatation or obstruction of the mitral orifice

Dr Israel T Dana, of Portland, Me, had under observation two sisters The mother died of organic heart disease Both of these sisters have had a mitral regurgitant murmur In the older sister the murmur after remaining five or six years disappeared It remained absent for one or two years and then returned, and has continued for the past two or three years In the second case, the murmur after having been present for five or six years disappeared, and has since remained absent He asked if it were possible that a murmur connected with organic heart disease should disappear with improvement of the health and reappear when the health again fails?

Dr Hosmer A Johnson, of Chicago, read a paper on

PNEUMATIC DIFFERENTIATION

In the absence of the author the paper was read by the secretary The author had compared the results obtained by the cabinet with those obtained by the Waldenburg apparatus, and he held that the former accomplished no more than the latter The pneumatic cabinet he considered cumbersome and expensive, with nothing especially to commend it in the treatment of pulmonary diseases

Dr John S Billings, U S A, read a paper on *Methods of Literary Research*

AFTERNOON SESSION

Dr H C Wood, of Philadelphia, read a paper on

THE ANTIPYRETIC TREATMENT OF FEVER

He had prepared certain propositions which he read and then gave what he thought to be the proof of their correctness *First*, Fever is a disturbance of calorification in which through the influence of the nervous system, heat dissipation and heat production are both affected If there be a fever which is produced by the direct action of a poison, independently of the nervous system, we have at present no proof of its existence In his experiments the agent used to produce the fever has been the pyrogenic principle found in ordinary commercial pepsin

Second Heat production is regulated by a nervous apparatus, our knowledge of which is still imperfect There is certainly an inhibitory centre which depresses or controls the production of heat It probably does this by acting upon the trophic cells of the gray matter of the spinal cord It is possible, also, that there is a centre which, when excited, increases tissue change, but its existence has not yet been proven The speaker than gave a resumé of the experiments which he had performed, which, in his opinion, proved the truth of the above proposition

Third Heat dissipation is regulated through the vaso motor system, so that vaso motor paralysis is followed by an enormous loss of animal heat, and under unfavorable circumstances by death from cold If section of the cord is made in such a way

as to get vaso motor paralysis without destruction of the respiratory centres, the heat dissipation rises enormously If the animal is kept in a temperature of 50° or 60° it dies in a few hours of progressive loss of heat If kept in a warm chamber it lives for days The cause of the rapid heat dissipation is the opening of the blood vessels of the surface of the body

When these remarks are applied to a study of antipyretics, it is seen that drugs may lower bodily temperature in health or in fever by increasing heat dissipation In this way act all agencies which cause vaso motor paralysis Antipyretics acting in this way may be called false antipyretics Then it is conceivable that there may be drugs which act on heat production through the inhibitory nerve apparatus, of which mention has been made Such drugs may for convenience be called true antipyretics Aconite veratrum viride and drugs of that class belong to the false antipyretics Whether or not there are any true antipyretics has been a question which we have been unable to answer With regard to antipyrin, certain experiments made in the University of Pennsylvania, seem to give some positive results Care must be exercised in these experiments not to confound a normal defervescence with the action of the drug administered *In the dog the use of antipyrin* diminishes both heat production and heat dissipation, the former being diminished more than the latter It is probable that heat production is primarily affected The question arises whether this result is due to an effect on the circulation? He had found that antipyrin had no effect upon the circulation The blood pressure was uninfluenced by its administration He therefore concluded that the action of antipyrin upon the bodily heat was entirely independent of any action upon the circulation, and the probabilities are, of course, that it acts through the nervous system Beyond this our present knowledge does not extend

DR FRANCIS MINOT, of Boston, read a paper on

THE TREATMENT OF TYPHOID FEVER BY ANTIPYRIN AND THALLIN

The paper was based on the observation of twenty-four cases treated in the Massachusetts General Hospital, the object of the study being to ascertain the proper dose of the drugs, their general and specific effects upon the patients, the results from their continued use as compared with those from their occasional employment, any unfavorable results, and the general effect of antipyrin and thallin upon the course of the disease

The following conclusions were reached 1 Both antipyrin and thallin have a remarkable power of reducing the temperature in typhoid fever 2 In no case was the use of these refrigerants apparently followed by any unfavorable effect upon the course of the disease 3 The general condition of the patient was more comfortable after taking antipyrin and thallin, which were often followed by sleep 4 The refrigerant medication by antipyrin and thallin appears to have no specific or decided effect upon the course or issue of typhoid fever It often contributes much to the patient's comfort, perhaps indirectly promotes his safety 5 The effect of antipyrin and thallin in promptly lowering the temperature shows that the danger in typhoid fever does not consist in high temperature alone, and that the latter is rather an index of the violence of the abnormal condition which we call fever, though, perhaps, adding somewhat to the danger 6 By the internal use of antipyrin and thallin, all the effects which are claimed for the treatment of typhoid fever by the cold bath are readily obtained without the trouble and inconvenience of the latter method, and without exposing the patient to the dangers of exhaustion and shock, consequent on the fatigue of removal from bed 7 These remedies may be given without danger to the youngest patients in suitable doses, and indeed, their beneficial effects are more decided and the unfavorable consequences are less observable than with adults

DR I E ATKINSON, of Baltimore said that, as regards the relative merits of antipyrin, and antifebrin, he thought that the tendency to chilling after the use of thallin is decidedly greater than after the use of antipyrin, while the latter is more apt to produce nausea and vomiting He disagreed with the statement that the use of these drugs can take the place of the external application of cold water Although with antipyretics we can reduce the temperature at pleasure, yet the duration of the case is not lessened, and in some cases it has been thought to have been prolonged

DR GEORGE L PEABODY, of New York, had found that a certain proportion of cases which do not bear the cold bath will bear the use of antipyretic drugs, while on the other hand, the bath may be used in a certain number of cases in which antipyretics cannot be applied From clinical experience, he was convinced that the cold bath accomplishes more than the simple reduction of temperature Its soothing effect upon the nervous system is greater than that accomplished by the reduction of temperature by antipyretic drugs Another important matter is, that since the introduction of these methods of antipyresis, the number of relapses seem to be greater and more fatal

DR WM M WELCH said that there is comparatively little evidence that the grave symptoms of fever are referable to the elevation of temperature There is no doubt that temperature of 110° to 113° produce serious symptoms, but whether or not ordinary temperatures of 105° to 107° exert any serious action on the body, is a question which is certainly unsettled It has been shown that rabbits can be kept in a box with a continuous rectal temperature of 107° for at least two weeks, provided the precaution is taken to keep the box well ventilated, and the animals supplied with moist food Patients may have a perfectly clear brain, and no grave symptoms with a temperature of 106° or 107° On the other hand, there are severe and fatal cases of typhoid fever in which the temperature has never registered a great height While in most cases there is a certain proportion between the height of the temperature and the severity of the disease, yet there are

certain cases where this proportion does not exist

Dr William Pepper said, that the action of these drugs seems to be purely through the nervous system He had seen no effect upon the circulation, upon the respiration, or upon the secretions save that of the skin Some of his observations have been of interest with reference to the relative value of the external use of cold water and the internal use of antipyretics In the sudden acute pneumonia of children with a temperature of 106° or 107° with initial convulsions, where the prompt and repeated use of cold baths has been without gratifying results, full doses of either of these antipyretics have produced a remarkably successful effect As to the ability of these agents to replace cold baths under all circumstances, the evidence is not adequate In the sudden hyperpyrexia occurring in the course of rheumatism, he was not prepared to accept the view that these drugs are capable of replacing the cold bath In these cases we have direct evidence that the high temperature is the direct cause of the symptoms at least of the severe nervous symptoms

Dr George B Shattuck had used both antipyrin and antifebrin largely, and it seemed to him that antifebrin offers all the advantages of antipyrin without its disadvantages It has none of the disadvantages which belong to thallin Three or four grains of antifebrin accomplishes the same results as are produced by a larger dose of the other drugs With reference to the point suggested by Dr Welch, he said that whether pyrexia is or is not a dangerous feature of the disease, we find clinically that where a patient has high fever, is irritable and uncomfortable, the administration of one of these antipyretics or the external use of cold water produces a tranquil and refreshing sleep, and the patient awakes in a condition much better to continue the struggle with the disease

Dr J C Wilson, of Philadelphia, referred to a recent observation which he had made as bearing on the question of heat dissipation He had lately been treating a case of typhoid fever, in which from time to time, antifebrin in 5-grain doses was given These were repeated whenever the temperature reached 104° This caused copious sweating with the usual reduction of temperature, amounting to 3½° or 4° On the last occasion $\frac{1}{96}$ of a grain of sulphate of atropia was given with the antifebrin No sweating occurred and the temperature was reduced only 1½°

Dr James T Wittaker, of Cincinnati, differed from those who seem to accept the view that fever is a neurosis We have no proof that the nerve centres are distinctly irritated, and we have no proof that the agents which reduce fever act directly on the nervous centres Is it not more probable, he asked, that the antipyretic action is really an antimicrotic action? We have some observations which go to show that the disease is caused by bacteria, or if not directly by bacteria by some of their products, the ptomaines Would it not be more rational to study the habits of these bacteria and address ourselves rather to the removal of the cause than to the counteracting of the effects?

Dr H M Lyman, of Chicago, was disposed to regard the great value of antipyretics as proceeding not so much from their power to reduce temperature as from their general effect, especially upon the nervous system He regarded them as valuable adjuvants in the treatment of disease, largely from their hypnotic and tranquilizing effect upon the nervous system to which allusion has already been made He had observed that in many instances in which in abrupt febrile affections relief has not been secured from antifebrin and antipyrin, this failure is frequently due to the presence of the condition we call rheumatic, and then salicylic acid gives the relief that we fail to get with the antipyretics

Dr John Guiteras said, that in treatment of the continued fevers of warm climates the results have been rather negative, and have showed the advantage of stopping the use of these drugs after they have been continued for a certain length of time He had been called in consultation where the drug had been continued for ten or fifteen days, each time that it was given producing a certain reduction of the temperature but having no permanent benefit, and the patients had begun to improve as soon as the drug was stopped The effect of cold water baths in these continued fevers of the South had seemed more beneficial If continued for two or three days they often favorably modify the course of the disease

Dr George L Peabody said, there was no question in his mind that a considerable proportion of cases of typhoid fever can be aborted by antiseptic treatment of the intestinal ulcers with naphtholin or resorcine For the last two years he had treated all cases coming under observation during the first ten days of the disease with a calomel purge (10 grs) followed by naphtholin in such doses that at least 70 or 80 grs are taken during the twenty four hours Under this treatment he had succeeded in aborting many cases in which the symptoms were quite pronounced

Dr James Tyson, of Philadelphia, reported a recent case of rheumatism, in which the temperature suddenly went up to 105°, with alarming brain symptoms Antifebrin in 5 grain doses failed to produce any effect The patient was then put into a cold bath, and the temperature of the water gradually reduced to 72° The discomfort experienced by the patient then prompted his removal from the bath The thermometer in the rectum showed a reduction of only ½°, but within the course of half an hour the temperature fell 3° The fall in temperature was followed by a disappearance of all the symptoms and the recovery of the patient

Dr Henry Hun, of Albany, reported some

CASES OF SEWER-GAS POISONING

The author reported in detail the histories of twenty-nine cases coming under his observation, in which various diseases appeared to have been due to the inhalation of sewer gas He thought it probable that the following diseases may result from severe gas poisoning vomiting and purging, separately or combined, general debility, fever, sore throat of a

diphtheritic type, neuralgia and perhaps, also, myelitis of the anterior horns These conditions are frequently combined Fever is frequently associated with the other symptoms There is one group of symptoms which is almost always present, that is loss of appetite, extreme prostration and pain in the head When this occurrs as a chronic condition we are justified in suspecting that the patient is suffering from sewer gas poisoning

DR ISRAEL S DANA, of Portland, Me, reported

A CASE OF ANEURISM OF THE ABDOMINAL AORTA

A man of 30, of previous robust health, was found August 6, 1886 emaciated, feeble, anemic, dyspeptic and with very frequent, unsteady and irregular pulse The most prominent symptom was a constant sensation of throbbing and pulsation centering in the epigastrium In August, 1884, he fell ten feet, striking on small of back, but felt as if hurt internally The sore spot remained Gradual deterioration of health occurred, until in latter part of June, 1886, he was utterly incapacitated from all labor Exploration of abdomen anteriorly revealed the existence of a small equably expansile tumor just above the level of the umbilicus Distinct blowing sound On examination posteriorly, there was found a distinct independent centre of motion and sound The sound was double, sharper and more intense than that heard in precordial region, and possessed a well-marked "booming" quality Diagnosis of small traumatic aneurism of abdominal aorta just after its passage through diaphragm was made Treatment consisted of absolute rest in bed for two months, restricted diet of bread, meat, milk and cocoa, limited amount, iodide of potassium 20 grs four times a day Immediate improvement ensued within first week, and continued gain in power, till by the middle of November he could walk and ride about carefully On May 9, 1887, physical examination revealed anteriorly, the existence of the aneurismal mass, perhaps a little diminished in size, while the blowing sound was scarcely audible The impulse and expansion were markedly reduced On examination posteriorly, the independent centre of pulsation and double sound was found, but both motion and sound were greatly reduced in amount, and the booming quality was gone

The chances of final complete recovery were not considered encouraging circumstances of patient not favorable to such rest, recreation and tranquility of mind as might be desirable, and even with all external conditions at the best there would yet be too many dangerous liabilities remaining, such as embolism, pyæmia, atheromatous, degeneration, etc The quick improvement under treatment is noticeable The patient himself attached great value to the iodide of potassium which he still takes, feeling so much better while taking it that he is unwilling to leave it off

(To be concluded)

FOREIGN CORRESPONDENCE

LETTER FROM STRASSBURG [1]

Prof E Fischer—Spiral Growth of Organs—Apparatus for detection of Spinal Curvature—Prof Luecke—Resection of Intestine for Gangrene—Fæcal Fistula—Ectopia of the Bladder—Stimulants in Pyæmia—Antisepsis—The Burger Hospital—Prof Freund—Septicæmia and Antisepsis—Hairpin Tumor—Von Recklinghausen—The Pathological Institute—Tumors of the Pancreas—Myositis Ossificans

Dear Doctor Fenger —Having completed my mission in Paris, I came directly to Strassburg, where I arrived April 1 My first call was on Prof E Fischer, who had just returned from Berlin, where he had spent five months in studying specimens in the different museums with reference to spiral growth, a subject to which he has called the attention of the profession in a lengthy monograph from his pen. Prof Fischer, who is well and favorably known in German surgical literature, is a good example of German industry and enthusiasm The doctrine which he advanced some time ago, that all organs during their growth, assume a spiral shape something like a cork-screw, and that the spiral curves always take a definite direction, right or left, according to their anatomical relations to the central axis, had to be demonstrated more thoroughly for his own satisfaction and for the purpose of giving this principle a practical application To do this he obtained a leave of absence, and for five months, at considerable expense, he studied his favorite subject in the different embryological, anatomical and pathological collections in Berlin The results of these researches have only served to confirm his views, and he has been able to show that in the fecundated ovum the spiral growth becomes apparent after the third segmentation, and that even the protoplasm in each individual cell is arranged in a spiral manner For more than two hours I listened patiently and interestedly to his remarks, and examined the specimens which he has utilized in illustrating his monograph As striking illustrations of spiral growth, he calls attention to the structure of the umbilical cord, the heart, the long bones, the bladder and the nerves Many deformities he attributes directly to an increase or dimunition of normal spiral curves, so for instance scoliosis and germ valyum and varum Professor Fischer has devoted a great deal of time to a study of lateral curvature of the spine, and has invented a most ingenious apparatus which enables him to detect a very slight degree of deviation, and thus resort to appropriate early treatment The patient is placed upon a platform divided into two equal parts, under each of which a scale is arranged so that when the patient is placed into a perfectly erect position in front of a perpendicular staff, the weight on each side can be accurately ascertained Asymmetry of the lower extremities is recognized as a frequent cause of scoliosis, and the deformity is at once improved, and further aggravation prevented, by supplying the

[1] By permission of Drs Fenger and Senn

shoe on the affected side with a sole of sufficient thickness to balance the length of the opposite limb Prof Fischer is a hard student, a conscientious worker and will not fail in making many more valuable contributions to surgical literature

The surgical wards of the Burger Hospital, in charge of Professor Luecke, are in a separate building, recently erected, and supplied with all modern improvements and conveniences The average number of surgical patients is 150 Prof Luecke, whom I had the pleasure of meeting in 1878, looks very much older, but his working capacity remains unimpaired He showed me a number of exceedingly interesting cases among them a resection of the intestine for gangrene, where twelve inches was removed in a case of strangulated hernia, the bowel sutured and returned The resection was done sixteen days after the herniotomy, a procedure which he prefers to immediate resection, and enterorrhaphy, as the intestine is in a better condition for such a serious operation, at the same time the surgeon is in a better condition to decide how much of the bowel must be removed In this case the wound of the second operation was nearly healed, the action from the bowels regular, appetite good, no tympanitis, all symptoms indicative of a speedy and permanent recovery A woman about 40 years of age, was shown, upon whom a gastro enterostomy had been performed one week ago The dressing was removed for the first time, and the wound was found united The case was considered favorable for a pylorectomy, but a direct examination showed that the disease had extended behind the stomach, rendering extirpation impossible, consequently Wolfler's operation was performed For a number of days after the operation the patient was nourished exclusively by rectal alimentation, at present she was allowed to take moderate quantities of food and experienced no difficulty in digestion The relief afforded by the operation was prompt, and has continued without interruption

In the case of a fecal fistula in a girl about 18 years of age, where all ordinary measures to close the abnormal passage had failed, a favorable result was obtained by opening the abdomen through the median line, separating the bowel from the abdominal wall, and suturing the bowel in the usual manner Attention was called to the importance of opening the abdomen some distance from the artificial anus, as such a procedure affords a better opportunity to ascertain the extent and nature of the adhesions, and affords greater facilities for their separation and the prevention of fecal extravasation during the operation In this case, not a single unpleasant symptom followed the operation

With great interest I examined two cases of ectopia of the bladder Both patients were females, one a child, the other an adult In the child, a number of operations had succeeded in forming a perfect anterior wall, thus converting the imperfect bladder into a convenient receptacle The artificial wall in the woman remained imperfect, which will necessitate further operative interference

I was informed that two cases of pyæmia, where the patients came into the hospital infected, had recovered, after a long illness, under the influence of large doses of stimulants In one case the presence of pulmonary infarcts was unmistakable, and yet complete recovery followed These cases only prove that even in pyæmia, recovery need not be despaired of in cases where life can be prolonged until a period of limitation is reached when the specific cause loses its toxic effect on the organism, is exhausted, and is no longer in a condition to furnish the material for the progressive production of the microbes

The antiseptic treatment in this hospital is rigidly and conscientiously followed, a circumstance which certainly must come in for a great share of the credit pertaining to the remarkable recoveries after the most serious and dangerous operations One forenoon I devoted to a visit to the gynecological and obstetrical wards, under the care of Professor Freund The wards are in a new building only recently occupied, and located *vis a vis* the Surgical Klinik The building is a model of its kind and a credit to the German Government, which has spared no expense in making it perfect as a centre for clinical teaching Professor Freund takes a just pride in the institution which has developed into such a magnificent hospital and school for teaching under his personal supervision, and is untiring in his efforts in pointing out its advantages and modern improvements In the lying in department the antiseptic precautions are so thoroughly carried out that puerperal sepsis has never been known to originate in the wards A small building, isolated from the main building, serves for the reception and treatment of infected patients from the city and the surrounding country, and here the student finds the only opportunity to study at the bedside and the post mortem room the infective diseases incident to childbed

There is certainly a great deal of truth in the statement made by the famous Robert Koch, in answer to my question relative to the nature of septicæmia, that this disease is beyond the grasp of the pathologist in Germany, as antisepsis had succeeded in almost exterminating the disease in that country I sympathize sincerely with the pathologists, but rejoice at the results obtained by Joseph Lister and his followers in expunging from the catalogue of diseases one of the most fatal and fearful complications of the obstetrical and surgical wards In the face of these facts who can doubt any longer the efficiency of antiseptic precautions in preventing infection? Who will dare to ridicule the honest, conscientious surgeon and obstetrician in his efforts to protect his patients against infection? Who will have the courage to recommend a pad of infective germs as a safe dressing for penetrating wounds of the abdomen? Let history, science, and the combined experiences of thousands of honest physicians and surgeons answer these questions

Professor Freund related to me the history of a very interesting case that recently came under his observation A patient was brought into the hospital suffering from all the symptoms of pyosalpinx Abdominal section was performed, and a careful digital exploration appeared to confirm the diagnosis

On one side of the uterus, corresponding to one of the tubes, a hard, adherent mass was found, which was removed entire with great difficulty, on account of firm universal adhesions, in the separation of which severe hæmorrhage was incurred After the mass was removed the large cavity was filled with a tam pon, and all bleeding arrested by compression and ligature Section of the mass revealed in its interior a hairpin This common instrument of destruction had evidently been used to produce abortion, had perforated the uterus and caused the suppurative parametritis—another sad illustration of the folly of women in attempting limitation of offspring

A number of recent laparotomies showed no temperature and were on a fair way to recovery All abdominal operations are performed under strict antiseptic precautions, with the exclusion of the doubtful spray I examined with interest numerous frozen sections illustrating the normal anatomy and various pathological conditions of the female pelvic organs, which were fastened upon a wire framework, according to the device of Professor Freund, and kept as wet specimens You will recollect that Pro fessor Winckel adopted this method of mounting in obtaining his photographic illustrations for his great atlas

A visit to the Pathological Institute brought me face to face with one of Germany's greatest patholo gists, the distinguished von Recklinghausen I found him smoking his morning cigar, but deeply engaged in his arduous work Previous experience satisfied me that the director of one of the best pathological museums would spare neither time nor labor to show me the most interesting specimens I found here the largest collection of specimens illustrative of diseases of the pancreas I was exceedingly anxious to ex amine the specimen of pancreatic calculi with ectasia of the common duct, but when we searched for it where it should naturally belong it could not be found, a circumstance which almost instantaneously changed the placid temper of the professor into a rage Shelf after shelf was examined, but that speci men, in some unaccountable way, had disappeared I suggested that we abandon the search but this only stimulated him to renewed energy, and I heard from behind the cases language more forcible than ele-gant, until the unhappy "devil" of the museum re membered the exact *locus* of the wandering pancreas, and he brought the specimen triumphantly to the ex-cited director, whose countenance at once assumed its wonted tranquil, peaceful aspect The average German professor is a typical representative of sys-tem and order, and the displacement of a specimen is considered in the light of a criminal offense, and, as the learned professor said on this occasion "So etwas darf hier nicht vorkommen "

In a short time three new specimens have been added to the pancreatic collection One of them consisisted of a solid tumor, probably malignant, in the head of the organ, with a large cyst on the peri-pheral side During life only the cyst was recog-nized, and after an exploratory puncture a probable cyst of the pancreas was diagnosticated Professor Luecke performed abdominal section, stitched the cyst to the wound, opened and drained it Next day *exitus letalis* The post mortem examination showed that the primary disease had originated in the head of the pancreas and had involved the adjacent tis-sues, the cyst had been caused, undoubtedly, by progressive destruction of the secretory structures of the pancreas and obstruction of the cystic duct The second specimen is a large cyst, removed post mor-tem, where no communication exists between the cyst and the duct The third specimen represents a primary carcinoma of the pancreas without the form-ation of cysts The more I study the etiology of cysts of the pancreas, the more I become convinced that simple obstruction is inadequate to cause a cys-tic dilatation of the duct, as in such cases, as long as the gland remains intact, the pancreatic juice is ab-sorbed, in other words, a retention cyst cannot be produced as long as auto absorption remains intact But, in cases in which the cause of the obstruction affects deleteriously the parenchyma of the organ, absorption no longer takes place, and the combined effect of obstruction and accumulation of the pro ducts of secretion from intact portions of the gland on the distal side of the obstruction, result in the formation of a retention cyst

This museum contains three beautiful specimens of myositis ossificans In all of them the production of new bone is most marked in the extensor muscles of the back and in the vicinity of the hip joint, in the latter location braces of new bone connect the pelvis with the femur, so that, with an intact hip joint, perfect immobilization of the thigh bone has taken place, always in a flexed position In regard to the true pathology and etiology of this singular disease, little or nothing is known At the meeting of the German Congress of Surgeons recently held in Berlin, Professor Helferich, of Greifswald, showed a young man suffering from this disease who had been under his observation for seven years The disease commenced as an acute attack resembling rheuma-tism, followed in a short time by production of bone along the course of the affected muscles It is more than probable that the ossifying process is limited to the connective tissue around and within the muscles, and that the muscular fibres disappear in consequence of pressure, atrophy, and interstitial absorption on the part of the new osteogenetic material

N SENN

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

[FROM OUR OWN CORRESPONDENT]

Cancer of the Pancreas—Epithelioma of Penis—Intubation, Feeding after Intubation, Statistics of Intubation, Pathology of Intubation

At a recent meeting of the New York County Medical Association, Dr Thomas C Taylor read the report of a case of *Cancer of the Pancreas*, with infil-tration of the omentum and walls of the stomach, along the greater curvature, occurring in a female of

30 years The case was interesting both on account of the infrequency of the affection and the obscurity of its diagnosis In this case, three important and common symptoms generally regarded as diagnostic of pancreatic cancer jaundice, œdema, and fat in the alvine discharges, were absent Dr Taylor thought Dr Costa's manner of diagnosticating these cases the most feasible—that by exclusion As to the possibility of prolonging life by operation in a case of cancer of the pancreas, if the diagnosis could be made early enough, the two cases reported by Billroth were of much interest, he had made a partial resection of the organ, removing the tail in one and a portion of the head in the other case, but, of course, not injuring the duct Both patients recovered from the immediate effects of the operation, but how long they lived, or whether the disease returned, is not stated Dr Taylor thought that when he first saw his case, but a very small portion of the head was involved, and that if the diagnosis could then have been made, it would have been an excellent opportunity to perform an operation similar to Billroth's

At the same meeting Dr J R MacGregor presented a portion of a *Penis Amputated for Epithelioma* At the operation care was taken to prevent subsequent constriction of the urethra in the stump, and thus far the result was satisfactory The chances were fair that the growth would not recur Dr J W S Gouley said it was of interest that in epithelioma of the glans or prepuce there is always antecedent balanitis or balano posthitis, and most cases occur in persons who have chronic balanitis, this condition being chiefly due to lack of cleanliness In such cases epithelioma develops rapidly, and soon involves both the mucous membrane and the corpora cavernosa In his experience, amputation, as usually resorted to in these cases, is insufficient, and is likely to be followed by a more or less rapid recurrence, which always commences at the end of the stump Atresia urethræ is also likely to be a very unpleasant consequence of the operation, and he related a case in which, although there was no return of the cancer, the patient died within two years from pyelo nephritis due to atresia thus produced In one case of amputation for epithelioma, he first used the écraseur to break up the cavernous bodies Then, leaving the urethra fully three quarters of an inch longer than the stump, he fastened it to the free extremities of the cavernous bodies On account of the frequency of recurrence, he determined to excise the whole penis in his next case, and in April, 1878, he did this operation on a patient 50 years old He dissected out the entire organ, without opening the cavernous bodies, and removed the crura and all About one half of the cavernous bodies had been invaded by the growth The patient was discharged cured within two months, but he knew nothing of the subsequent history of the case It seemed to him that such a radical operation was the *best* safeguard against recurrence, for if the slightest deposit remained the growth would recur In the majority of cases it was not only justifiable, but the most proper measure to adopt It is not a formidable operation, and in his case the patient made a rapid recovery

Dr Bryant referred to three cases of amputation of the penis in his own practice In two the operation was done for cancer involving the glans and anterior portion of the organ, and in the third for general carcinoma, involving not only the penis, but the whole system He believed that the entire removal of the penis is the only ultimately safe procedure But if the growth be very slight, it might be allowable to consult the patient's wishes, and if he object, make the amputation pre scrotal

Intubation was the subject of discussion at the first meeting of the Academy of Medicine in June Dr F Huber's paper was a study of forty-seven cases from his own practice Of these twenty nine, with eleven recoveries, were in children under 3 years of age, and eighteen, with nine recoveries, in children of 3 years or over Of the children under 3 years, one was 9½ months old, one 10½ months, two 11 months, one 1 year, two 2 years, two 2½ years, and two 2 years and 8 months old Of all the children that he had been of late called upon to treat for laryngeal stenosis, he had found it necessary to resort to intubation in only one out of every three or four cases, and he thought it should not be done until dangerous symptoms set in He used it in the same class of cases in which, up to a year ago, he would have performed tracheotomy The dyspnœa is as effectively relieved by intubation as by tracheotomy The utility of intubation was fully established, and it has now passed the experimental stage One of the most serious accidents that can occur is the pushing of dislodged membrane before the tube, and in such a case Dr E D Ferguson, of Troy, performed tracheotomy Several deaths have been reported from this accident, and Dr Waxham has recently devised a long tracheal forceps for removing the membrane in such cases In a case under his care he gave the child brandy, which excited such a fit of coughing as to expel both the tube and the membrane As a rule, the tube can be dispensed with at a much earlier date than the tracheotomy tube If respiration continues free, it should generally be allowed to remain until at least the fifth or sixth day, but if the breathing becomes noisy, it should be promptly removed and afterwards reintroduced, if necessary When there are diphtheritic patches in the nose or pharynx, it is advisable, as a rule, to leave the tube in position until they disappear In intubation, as in tracheotomy, the prognosis is more favorable when there is simply local obstruction in the larynx than in cases of marked constitutional infection from diphtheritic poison No positive prognosis should ever be made until 48 hours after intubation Intubation, he believes, will save many cases in which tracheotomy will not be permitted, and many which would die if the latter were performed, especially in children under 3 years No age appears a contraindication to intubation Of 12 cases in which he had done tracheotomy, 10 died He felt warranted in assigning to intubation a much higher position As regards medicinal treatment, he uses bichloride of mercury throughout the disease, whether intubation were prac

tised or not He gives gr ⅙–ss, and in severe cases gr j, in divided doses, in twenty four hours If there be much dysphagia, he uses tablet triturates, gr $\frac{1}{10}$ each, mixed with sugar, and placed dry upon the tongue With extensive diphtheritic membranes in the fauces he also uses tincture of iron and chlorate of potassium In threatened heart failure he uses brandy, caffeine, etc If the temperature be very high, antipyretics are used, by the mouth or rectum He also uses the steam atomizer to produce a moist vapor

Dr J O'Dwyer read a paper on *Feeding after Intubation* As a rule, solids and semi-solids are taken much better than liquids after intubation In a number of cases he had removed the tube in order to give nourishment, but the results were scarcely better than when it was in position Sometimes swallowing is easier after than before intubation, on account of the relief afforded to the urgent dyspnœa The longer the tube remains in position, the easier it generally is to swallow When the patient is old enough to understand, he should be instructed to drink rapidly, and to take as much fluid as possible at one time Sometimes he uses rectal alimentation, but very seldom uses the stomach tube He does not think that food is a cause of pneumonia after intubation, as he has never seen any evidence of milk or other nourishment being found in the minute bronchi He had known an adult patient to wear a tube for more than ten months, who not only did not have pneumonia, but meanwhile was cured of bronchitis, which he had when the tube was put in The secretions, he thinks, are the source of the pneumonia met with after intubation, they being aspirated into the finer bronchi It is due primarily to the presence of the tube, because it impairs the patient's power of expulsion As to removing membranes with the forceps, the subglottic division of the tube is of such narrow calibre that it is practically impossible to use this instrument, and he has devised a flexible apparatus for this purpose, somewhat on the principle of the umbrella probang

Dr Dillon Brown read a paper on the *Statistical Records of Intubation* So far as he had been able to ascertain, 760 cases, by 54 different operators, had been reported, he had tabulated 502 cases—211, or 27 07 per cent, had recovered The average age in fatal cases was 3 years and 2 months, in recoveries, 4 years and 1 month In the recoveries intubation was resorted to at an average period of 2 days and 9 hours after symptoms of laryngeal stenosis first appeared, and in fatal cases at an average period of 1 day and 19 hours In the fatal cases the average time between intubation and death was 2 days and 8 hours, in the recoveries the tube was worn on an average for 5 days and 3½ hours O'Dwyer had operated 78 times, Waxham 106, Dillon Brown 84, and Huber 47 times Extension of the membranes to the bronchi was the most frequent cause of death He believed that pneumonia, when present, was secondary in character

Dr W P Northrup read a paper on the *Pathological Anatomy of the Respiratory Tract after Death from Laryngeal Diphtheria and Intubation* Since he read his paper on this subject before the Academy in December, in which he reported 87 cases, 20 additional fatal cases had occurred at the New York Foundling Asylum, to which he is pathologist The cause of this large number during so short a period as four months was the occurrence of diphtheria in connection with a fatal epidemic of measles and scarlet fever In his former paper he stated that he had never met with ulcers of the trachea, but in the 20 cases now reported for the first time there were deep ulcers, laying bare the rings of the trachea, in five cases He had not met with ulceration of any consequence caused by the head of the tube, nothing more than necrosis of the epithelium He had seen no evidence of aspiration pneumonia, as it had been called, due to the entrance of fluids into the finer bronchi

Dr Caillé had performed tracheotomy in 21 cases, with 5 recoveries, and intubation in 16 cases, with 6 recoveries In his cases of intubation diphtheritic membranes were observed on the nares or pharynx in nine cases In most of the cases intubation was done rather late He believed that all the patients would have died without surgical interference, and that one who died would have been saved if intubation had been done earlier The cause of death after intubation was catarrhal pneumonia in a majority of his cases Most of the children who died had taken liquids, and of late he had allowed only solids cut up fine, with ice to allay thirst Since doing this his results were better P B P

BERGEON'S METHOD

Dear Sir —Permit me briefly to call attention to a few points in the preparation of gas for Bergeon's treatment After trying several methods I have, by travelling in a circle, again reached and for the present settled upon, marble chips and H_2SO_4 for generating the CO_2

The objection which Dr Babcock[1] makes regarding the irritating properties of the gas made from mineral acids is, in my practice, entirely avoided A gas which made his "nostrils sting" was clearly unfit for use whether there were enteric ulcerations or not I have discarded HCl and use only H_2SO_4 (C P) because the by-products, (such as free chlorine gas) are much harder to get rid of with the former I use a large mouthed half gallon generating bottle, in which the marble chips (not dust) are placed This is connected with the first wash bottle, (of which there are four, half gallon size,) filled with a strong solution of sodium bicarbonate Any acid fumes which are carried through would combine with the sodium liberating pure CO_2 The next two wash bottles are filled with simple water, unless it is desired to eliminate the H_2S, which is sometimes formed, in which case Ferric sulphate can be dissolved in one of them As H_2S is not objectionable this is unnecessary The last wash bottle is filled with the sulphur water, natural or artificial, which it is decided to use I am using both, and have but little choice, except that the artificial water can be

[1] JOURNAL, May 21, 1887, p 582

made to impregnate the gas much more strongly with H S, and is much cheaper

Everything being in readiness, and the gas bag connected the H SO, is poured into the generating bottle The marble chips should be previously tilted to one side of the bottle and made to remain there as much as possible by gently returning the bottle to the upright position This prevents too rapid evolution of gas, and when the marble in the bottom of the bottle has been utilized fresh marble can be precipitated into the acid by gently shaking it If the evolution of gas is slow it will be sufficiently pure for all practical purposes If it bubbles through rapidly and violently the wash bottles will do but little good, and the gas will be pungent and irritating The number of wash bottles could be increased to half a dozen if it was not thought to be properly washed

I have had no "colicky pains" reported as a result of the gaseous injections, although I send away from my office bags large enough to last patients from two to three days I think the reason is that my gas bags are of heavy rubber, through which osmosis must be difficult, and to any appreciable extent, perhaps impossible

I have nothing to report clinically, except that all the patients upon whom I have used this treatment have shown improvement in some of the symptoms I am not prepared to say that there has been arrest in any case, though one patient has used it faithfully for seven weeks* It is, of course, too soon to express a final verdict, and we can only work on, hoping that it will prove something more than another chimera added to the long list of "consumption specifics" If its power of controlling symptoms should prove to be reliable, and prove to be its only value, Bergeon would still deserve well of his generation Respectfully,

G W McCaskey, M D

Fort Wayne, Ind , May 24, 1887

TAPPING VS INCISION OF THE CYST IN OVARIOTOMY

Dear Sir —In the letter of Dr N Senn, published in The Journal of June 4, there occur on page 641, in reference to an ovariotomy by Mr Langton, the following remarks "The abdomen was opened by an incision through the linea alba about four inches in length, and the cyst tapped with the large trocar of Spencer Wells The puncture was followed by a free escape of fluid along the sides of the trocar, and some of it entered the abdominal cavity, and the wound was freely irrigated with the cyst contents

It has always seemed to me that the use of a large trocar with a truncated cutting edge in tapping a tense cyst is attended invariably by extravasation of fluid, and consequently increases the risk of peritonitis When the cyst contents are fluid, the patient should either be placed upon her side during the tapping, and proper precautions adopted to prevent entrance of fluid into the abdominal cavity, or the cyst should be emptied sufficiently to bring it into the wound by the use of a small trocar or by aspiration In case the contents are colloid they will escape through no tube, and incision of the cyst with the patient on her side, and traction upon the cyst wall, so as to keep it in uninterrupted accurate contact with the abdominal wall, are the only measures which will accomplish the desired object with safety "

I heartily endorse the foregoing suggestions of Prof Senn Having for many years observed the inadequacy of the various forms of trocar in preventing the escape of cystic fluid along the sides of the instrument, I have latterly dispensed with it entirely in some cases, and opened the cyst with a knife instead Dr Carl Braun uses the same method

The cyst having been exposed and the investigation of adhesions finished, a *dry* piece of antiseptic gauze folded into a pad of eight or more thicknesses is placed between the cyst and the incised abdominal wall on the side towards the operator The patient is then rolled strongly over on the corresponding side, and the cyst pressed forward into the wound by the hand of an assistant applied against the flank At a selected spot a small incision or puncture is made with the point of knife, the opening being subsequently enlarged to any extent desired Besides the dry pad, and the intra abdominal pressure of the cyst, an additional guard against the entrance of cystic fluid into the peritoneal cavity may be furnished in the following manner Take a piece of tin plate eight or ten inches long and four inches wide, and bend it lengthwise into the form of a half cylinder The end of this trough, held against the cyst immediately below the point of the intended incision, will serve to convey any fluid which may possibly escape from the cut away from the field of operation This device will be found of great service in whatever manner the cyst may be opened

So soon as the cyst wall becomes sufficiently relaxed, I seize it in folds with strong dull toothed vulsella, and by constant traction keep the opening and collapsing cyst outside the abdominal wound until complete extraction is accomplished

A Reeves Jackson, M D

271 Michigan Ave , Chicago

* This patient died June 5th

BOOK REVIEWS

Diseases of Women A handbook for physicians and Students By Dr F Winckel, Professor of Gynæcology, and Director of the Royal University Clinic in Munich Authorized Translation by J H Williamson, M D , Resident Physician Allegheny General Hospital, Allegheny, Pennsylvania Under the supervision of Theophilus Parvin, M D , Professor of Obstetrics and Diseases of Women and Children in Jefferson Medical College, Philadelphia 8vo , pp xxix—674 Philadelphia P Blakiston, Son & Co 1887

It is a little more than a year since Professor Winckel's work was issued in Leipsig As a teacher of obstetrics and gynæcology he has but few rivals,

and his numerous contributions to the literature of these subjects have made his name familiar to every reading physician And as of late years obstetrics and gynæcology seem to have taken a new hold on the American Physicians, it seems peculiarly fitting that this work should have been translated in this country Still better would it have been had the work been carefully annotated

No one can read this book without being interested and instructed Nor will one fail to be impressed with the idea—which is a fact—that the author is a most conservative gynæcologist, and there is not that neglect of gynæcological medicine for gynæcological surgery which many would possibly wish for The reader will find here no encouragement for useless and reckless laparotomies, Tait, Battey and Hegar operations It is pleasing to note that the author speaks of Sims in the very highest terms, and says "We are indebted to the American, Marion Sims, more than to any one else, for a large part of our knowledge of, and progress in the treatment of diseases of women"

As a whole, the book is excellent It would have been better, however, had more space been devoted to some subjects, as, for example, the varieties of salpingitis, and to tumors of the mammary gland And it would have been well had the proof-reading been done by one familiar with German

CHICAGO June 7, 1887

This certifies that I have carefully examined the accounts of R J Dunglison Treasurer of the American Medical Association to this date, and find them accurately added and properly vouched and that there is in his hands a balance of one thousand four hundred and three dollars and seventy seven cents ($1 403 77)

(Signed) ALONZO GARCELON,
Chairman of Auditing Committee

CORRECTION —At the request of Dr B A Watson, of Jersey City, the name of Dr L B Godfrey, of Camden, N J, has been substituted for his own, as the representative of New Jersey on the committee on State Medicine

MISCELLANEOUS.

PRACTICAL RESULTS IN RESTRICTING DIPHTHERIA —Bearing on the communicability of diphtheria and the practicability of its restriction, at a meeting of the state Medical Society of Michigan, May 13, 1887, Dr Baker presented a table and a diagram based on a compilation of reports by local health officers in Michigan for the year 1886 They exhibit the results of isolation and disinfection in outbreaks of diphtheria In the 102 outbreaks where isolation or disinfection, or both, were neglected, the average *cases* per outbreak were a little over 16, and the average *deaths* were 3 23, while in the 116 outbreaks in which isolation and disinfection were both enforced, the average *cases* per outbreak was 2 86,

and the average *deaths* were 66, indicating a saving of over 13 cases and 2 57 deaths per outbreak, or 1,545 cases and 298 deaths during the year, by isolation and disinfection in the 116 outbreaks, compared with those in which nothing was done

TABLE —Diphtheria in Michigan in 1886 Exhibiting the average numbers of cases and deaths per outbreak, 1, in all the 461 outbreaks reported, 2, in the 243 outbreaks in which it is doubtful whether or not disinfection and isolation were secured, 3, in the 102 outbreaks in which isolation or disinfection, or both, were neglected, and 4 in the outbreaks in which isolation and disinfection were both enforced Compiled in the office of the Secretary of the State Board of Health, from reports made by local health officers

	(1) All outbreaks [1] (461 outbreaks)		(2) Isolation or disinfection not mentioned or statements doubtful [2] (243 outbreaks)		(3) Isolation or disinfection or both neglected (102 outbreaks)		(4) Isolation and disinfection both enforced (116 outbreaks)	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
Totals	3,085	656	1 103	250	1 650	379	332	77
Averages	6 69	1 42	4 54	1 03	16 18	3 23	2 86	66

[1] These do not include the cases in Detroit and Grand Rapids

[2] It is possible that, in giving the public the benefit of the doubt, cases are sometimes reported diphtheritic which ultimately prove otherwise Many of these being limited to one or two cases, may bring the averages in these columns concerning which least is known below what they really should be All cases and deaths concerning which positive statements were made by health officers are included in the columns marked 3 and 4

THE RUSH MONUMENT —The State Medical Society of California at the recent session in San Francisco, April 20, unanimously adopted resolutions heartily approving the project of erecting a statue of "the immortal Benjamin Rush," in the City of Washington, and requesting the various medical journals to call upon every physician in the State, to contribute the very modest sum of one dollar each to which the subscription has been limited

MEDICO LEGAL SOCIETY OF CHICAGO —At the annual meeting of this Society held June 4, the following officers were elected for the ensuing year President, E J Doering, M D , First Vice President, Boerne Bettman, M D , Second Vice President, Erie Winters, Esq , Treasurer, L L McArthur, M D , and Secretary, Scott Helm, M D

MERITED HONORS TO PROFESSOR ESMARCH — Letters of Nobility have been given by the Emperor of Germany to F Esmarch, Professor of Surgery of the Faculty of Medicine at Kiel

MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA will hold its twentieth annual meeting at the White Sulphur Springs, W Va , July 13, 14 and 15, 1887 President, S L Jepson, of Wheeling, and Secretary, J L Fullerton, of Charleston

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U S ARMY, FROM JUNE 11 1887, TO JUNE 24 1887

Col J H Baxter, chief Medical Purveyor, to proceed to New York City for the purpose of inspecting the medical purveying depot at that place S O 133, A G O , June 10, 1887

Par 15, S O 52, A G O , March 5, 1887, is so amended by Par 9, S O 133, A G O , June 10, 1887, as to direct that Major Chas H Alder, Surgeon, be relieved from duty in Dept of Dak about June 20, 1887, and he is granted leave of absence from the date when so relieved, to include August 27, 1887

Major B E Fryer, Surgeon, found incapacitated for active service by an Army Retiring Board, and granted leave of absence until further orders on account of disability S O 133, A G O June 10, 1887

Capt Jno D Hall, Asst Surgeon, leave of absence extended one month S O 136, A G O , June 14, 1887

Major J H Bartholf, Surgeon, granted leave of absence for two months, to take effect about July 5, 1887 S O 141, A G O , June 20, 1887

Capt Chas Richard, Asst Surgeon, sick leave extended two months, on surgeon's certificate of disability S O 139, A G O , June 17, 1887

Capt Jno J Cochran, Asst Surgeon, granted leave of absence for one month S O 143, A G O , June 22, 1887

First Lieut W C Borden, Asst Surgeon, granted leave of absence for one month S O 135, A G O , June 16, 1887

First Lieut Wm N Suter, Asst Surgeon, designated as medical officer for the rifle camp at Creedmoor, N Y , July 5, 1887 S O 124, Div Atlantic, June 21, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE TWO WEEKS ENDING JUNE 25 1887

Surgeon Thomas C Walton, ordered June 15 for examination preliminary to promotion as Medical Inspector

Surgeon A F Price, detached from special duty at Annapolis, Md , proceed home and wait orders

Surgeon James M Flint, detached from the "Albatross," and ordered to the Smithsonian Institution

P A Surgeon W G Willson, ordered to the receiving ship "Independence," Mare Island, Cal

Medical Inspector C J Cleborne, ordered for examination preliminary to promotion as Medical Director

P A Surgeon G P Lumsden, ordered to receiving ship "Franklin," Norfolk, Va

Medical Director P J Horwitz, permission to leave the United States for six months

Asst Surgeon H N T Harris, commissioned Asst Surgeon in the Navy June 13, 1887

Medical Inspector J C Spear, detached from Naval Laboratory, and granted three months' leave

Medical Director Delavan Bloodgood, detached from Naval Hospital, Norfolk, Va , and to the Naval Laboratory

Medical Inspector Michael Bradley, ordered to Naval Hospital, Norfolk, Va

P A Surgeon H G Beyer, remain on present duty until September 1, 1887

P A Surgeon C G Herndon, remain on present duty until June 17, 1888

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED JUNE 18, 1887

Asst Surgeon W D Bratton, to proceed to Seattle, W T , on special duty June 8, 1887 When relieved to rejoin station at San Francisco, Cal June 11, 1887

Asst Surgeon R B Watkins, granted leave of absence for thirty days June 8, 1887

Asst Surgeon F C Heath, to proceed to Marine Hospital, Detroit, Mich , for temporary duty June 17, 1887

CORRIGENDA

In THE JOURNAL, June 25, p 719, the first line of quotation top first column should read "A very little little let us do"

In the list of contributors to the Rush Monument Fund, given in the issue of the 25th June, No 26, Vol 8 the name of John E Bready M D , of the Marine Hospital Service, is erroneously given as J E Bradly

Dr Henry O Marcy's name was inadvertently omitted in the signatures to the report of the committee on memorializing Congress relative to medical and sanitary service on board immigrant passenger vessels, as published in THE JOURNAL June 25 Dr Marcy has been a member of the committee from the first, and has heartily cooperated in its work and report

ADDRESSES

ADDRESS IN OBSTETRICS AND GYNECOLOGY

Delivered before the Thirty eighth Annual Meeting of the American Medical Association, June, 1887

BY I M JOHNSON, M D,

OF KANSAS CITY MO

The past year has given few, if any, remarkable discoveries, either in gynecology or obstetrics In the domain of gynecology, general attention is being devoted to tubal diseases and their operative treatment The greatest difficulty is, evidently, in correct diagnosis Diagnosis rendered reasonably certain, the removal of the Fallopian tubes is not especially difficult or dangerous

OVARIOTOMY

In ovariotomy it would seem that all has been accomplished that is possible, and it is not improbable that the astonishing success of the operation may lead to the too frequent extirpation of the ovaries for supposed cystic degeneration, enlargement, congestion, etc The practice of leaving the apparently undiscovered portion of the ovary when possible, in the extirpation of ovarian cysts, as recommended by Schroeder, is questionable It is probable that time will prove the safer practice to be the removal of the entire organ Electricity as a therapeutic agent in gynecology is well established

HOT WATER IN SHOCK

Dr Wylie (*Transactions of the Obstetrical Society of New York*, Nov 16, 1886), reports a case of laparotomy for the removal of a diffuse sarcoma of the pelvic organs, during the progress of which, there was considerable blood lost from vessels that could not be secured The patient became collapsed, had a feeble rapid pulse, was cold and bathed in perspiration A large quantity of water at 110° F was introduced into the abominal cavity through a large rubber tube connected with a bag holding about a gollon of warm water The woman rallied promptly, and the hæmorrhage was checked After the operation was finished, an additional quantity of water at 110° F was pumped into the abdominal cavity, and allowed to run out again Dr Wylie called attention to the fact that he used the hot water *not* as a *hæmostatic* but simply with the view of counteracting shock The known physiological action of warm water would suggest it as a potent agent in the treatment of shock Notwithstanding Dr Wylie states that he did not use the warm water as a hæmostatic, he informs us that the hæmorrhage was checked Heat was also communicated to the body, and it is probable that a portion of the water was absorbed entered the circulation, and in that way compensation in a degree for the loss of blood.

COCAINE IN GYNECOLOGY

Dr Cleveland (*Trans Obstet Society of New York*), has operated in two cases of lacerate cervix, local anæsthesia being induced by the application of a 20 per cent solution of cocaine, the patient experiencing little or no pain A tampon saturated with the solution was applied to the cervix, and left for fifteen or twenty minutes I have witnessed two operations for lacerate cervix, in which cocaine was used as a local anæsthetic, with satisfactory results

NITRATE OF SILVER IN RECENT LACERATIONS

Dr L Wilson (American Gynecological Society), advocates the use of nitrate of silver ℥j to ℥j water in early discovered lacerations of the cervix He recommends that the surface be carefully cleansed and dried, then paint the surface well with the solution of silver The application is made every four or five days, until cicatrization is established

Alexander's Operation is still on trial, and will probably not stand the test of time

Hysterectomy is receiving the attention and approbation of many of the able members of the profession at home and abroad, and the danger is that its popularity may lead to the abuse of the operation.

CÆSAREAN SECTION

In the domain of obstetrics, when dystocia is the result of abnormal conditions of the parturient canal, whether in the bony or soft tissues, to the extent that labor cannot be terminated by the conservative operations of the forceps or version, the profession is looking with a degree of favor toward the Sanger Leopold, or improved Cæsarean operation.

NEW PATHOLOGY OF LABOR

In the March and April numbers of the *American Journal of Obstetrics* may be found the most interesting, and probably the most important contribution of the year, by A F A King, of Washington City, entitled "A New Explanation of the Renal Troubles, Eclampsia, and other Pathological Phenomena of Pregnancy and Labor" The purpose of the paper is to present a new and more satisfactory explanation of the etiological relation between pregnancy and the nephritic derangements that so often attend it.

The paper does not deal with renal difficulties alone, but with other pathological states as well

Dr King's theory, briefly stated, is that the disturbances in the renal circulation and functions are produced chiefly by pressure of the gravid uterus upon the abdominal aorta or its branches, or upon the vena cava or its branches, or upon both or all of these, in consequence of the child and womb not maintaining during pregnancy, their normal lateral obliquity above the pelvic brim This, he says, is the pith of the whole matter He claims that the normal position of the child in the uterus during pregnancy, before labor begins is dorso anterior, of an oblique presentation, commonly known as a transverse presentation Therefore a head presenting toward the centre of the pelvic canal and os uteri, with the long axis of the child parallel with the axis of the superior strait is abnormal The normal position of the gravid uterus as defined by Dr King during the latter months of pregnancy, before labor begins, is the lateral oblique position corresponding more or less with the oblique position of the child The fundus being directed toward the right or the left side of the lumbar vertebra, and the lower segment of the uterus, with the contained head of the child should rest during pregnancy upon one of the iliac fossa, and that this is the normal condition both in the primipara and multipara

In other words, that there is no physiological reason, why in multipara the head of the child should rest during pregnagcy upon one of the iliac fossa and in the primipara, the lower segment of the uterus and contained head should descend into the pelvic cavity three or four months before full term, and if this obliquity of the womb and child be maintained during pregnancy there can be no injurious compression on any of the blood vessels, lymphatics or the uterus But with the womb and fœtus with their long axis in line with the axis of the plane of the pelvic brim, the vessels both arterial and venous would of necessity be pressed upon, and their function seriously interfered with Dr King hopes to show that eclampsia during pregnancy and labor, and their alleged preceding pathological states may be traced back to mal position, to the presentation of one end of the fœtal ovoid instead of an oblique presentation Dr King maintains, also, that premature distention of the cervical canal and lower uterine segment, and the premature descent of the lower end of the fœtal ovoid below the pelvic brim are sufficient to account for uterine irritation

So, whether the convulsions be due to uræmic intoxication, to uterine irritation, to cerebral hyperæmia or reflex local irritation in other viscera, or several of these coincidently, they may all be accounted for by pressure of the gravid uterus and child when the normal obliquity is wanting The causes of the disturbance of the normal lateral obliquity of the womb and child, and consequent premature descent below the pelvic brim, especially in primiparæ, are, according to Dr King, dress, corsets, etc

The question suggested by Dr King's paper, to be answered in the future, is Does eclampsia during pregnancy and labor, and their alleged preceding pathological states, occur in cases of transverse presentation when the uterus and child are wholly above the pelvic brim during the last months of pregnancy up to the time that labor begins? In discussing this part of the subject he refers to the fact, that obstetrical writers and teachers, when discussing the obstetrical treatment of eclampsia, confine their remarks almost exclusively to head presentations In regard to the obstetrical indications in transverse presentations they are silent In short, in a table of 300,018 labor cases collected by Dr King, with 212 cases of eclampsia, there is only one distinctly isolated coincidence occurring of eclampsia and transverse presentation during labor

I will not occupy your time, gentlemen, with a further review of the literature of the progress of obstetrics for the past year with which all are familiar I wish, however, to call attention to a few unsettled practical questions pertaining to the

MANAGEMENT OF THE NORMAL THIRD STAGE, AND THE PUERPERAL STATE

In the management of the normal third stage of labor and puerperal state should ergot be given? The profession is not agreed with reference to this question, some advocate the use of ergot before the close of the third stage, others immediately upon the expulsion of the placenta, and still a third class is not in favor of the entire administration of the drug

These differences are probably the outgrowth of opinions entertained by the profession in regard to the physiology of the third stage of labor and puerperal state, or the action of ergot All are familiar with the fact, that immediately following the expulsion of the child, there is a period of lassitude and repose This repose is necessary for the restoration of uterine contraction which is wanted for the expulsion of the placenta, and retraction to secure against hæmorrhage and septicæmia This end can only be physiologically attained, as all clinicians well know, by a process of rhythmical contractions of the uterus The blood circulating in the uterus for the nutrition of the child is now superfluous and has to be disposed of To this end the uterine muscles retract and the blood contained in the sinuses is forced out into the cavity of the uterus This being the physiological action of the uterus, why use ergot in the normal third stage, or puerperal state?

Are there not several objections to the routine use of the drug? Ergotism once established, is beyond control, it will run its course Ergotic contraction of the uterus is tetanic in character, and does not observe the physiological character of rhythmical contraction and relaxation, and further, the tetanic contraction of the non-striated muscular fibres of the uterus may be followed by loss of contractile power, a condition that tends to secondary hæmorrhage, and certainly retards the processes of involution

The *management of the placenta* has given rise to considerable discussion for the last few years The older members of the profession are inclined to deliver the placenta by early and gentle traction upon

the cord, and knead the uterus well in the meantime to secure good retraction The delivery of the placenta should not be deferred longer than ten or fifteen minutes After pains, physiologically considered, are salutary rather than otherwise, and if good uterine contraction has been secured seldom require treatment

The parturient woman should be kept perfectly quiet for a few days, and the second or third day she should be encouraged to sit upon the vessel when passing urine so that clots, if there be any in the vagina, may pass away The patient should be well nourished during the puerperal period

There is diversity of opinion as to the utility of *vaginal and intra uterine injections* during the puerperal period The application of antiseptic principles in obstetrics is no longer an open question The decided reduction of mortality in hospital and private practice following their use is an unanswerable argument in their favor, and the profession would probably differ less about the antiseptic treatment if a broader view of the subject was taken, and did not confound the principle of the treatment with the doctor's method of carrying it out The principle of the treatment teaches that everything is more or less *dangerous* that is *not necessary* The danger of prophylactic intra uterine injections has been demonstrated by Hoffmeier, who, in a series of over 200 cases, administered an intra uterine injection as soon as labor was completed, and in about the same number of cases omitted the injection The mortality was 50 per cent. greater in the cases that were treated by the intra uterine injections

The essence of the principal is to protect the woman by scrupulous cleanliness, and *every* other possible means from septic organisms or products, and their poisonous action Herein lies the success of modes of treatment which at first view appear to be in contra distinction to the antiseptic principle

---

LECTURE ON SUBCUTANEOUS BLOOD-INJECTIONS, SALT WATER INFUSION, AND INTRA-VENOUS TRANSFUSION[1]

BY PROF DR H von ZIEMSSEN,

DIRECTOR OF THE MEDICAL CLINIC IN MUNICH

The diseased conditions in which a renewal or repair of the blood seems necessary are so numerous, that the pertinacity with which the question of transfusion is again and again brought before the physician, despite repeated reverses, is easily explained It is well known that the enthusiasm over the transfusion of the blood of animals (such as sheep), into the human circulation, was brought to an end by the dangers of the operation, and by the publication of the works of Landois, Ponfick, and Panum, which showed that the blood of one species cannot be safely transfused into another species

At this time (1870–1873) I was experimenting with subcutaneous blood injections, and made a series of subcutaneous injections of animals' blood (lamb, calf, cow) in cases of various diseases in men The results were anything but satisfactory, as on the one hand there were no noteworthy favorable results, and on the other hand there was the same series of bad symptoms seen in intra-venous transfusion to day fever, hæmoglobinuria, irritation of the skin, urticaria, and suppuration at the points of injection In a very anæmic case of Bright's disease the injection of 50 grammes of lamb's blood caused a severe phlegmon But Panum, Ponfick and Landois have cleared up the whole question, they have laid down the most certain rules for the judging of all questions which come up in this matter, and we may predicate the following as certain Defibrinated blood of the same species, rich in oxygen, brought into the circulation under the necessary precautions, can not only guard against death from hæmorrhage, but also serve as an important means for reparation of function The blood of another species may also prevent death from hæmorrhage, but does not assist functional repair, because the foreign blood-cells break down and are excreted The hæmoglobin of the blood cells is partly taken up by the internal organs, especially by the spleen, and disappears here, but the greater part is excreted by the kidneys, and hæmoglobinuria results The kidneys show hæmoglobin infarcts, and in consequence of coagulation of fibrin thromboses and hæmorrhagic infarcts are also found in the lungs etc As the cause of these coagulations in the circulating blood, Alexander Schmidt and his school have found a fibrin ferment, which is due to the breaking down of the white blood cells The dissolution of the leucocytes begins at the moment when they escape from the vessels, and the ferment arising from them begins its work immediately upon the fibrinogenous substance, and produces the fibrin clot in the escaped blood With the coagulation of the fibrin the ferment exhausts itself for the most part, so that whipped blood, defibrinated, contains only a small amount of fibrin ferment, which is innocuous to the circulating blood It acts much more injuriously on fresh warm expressed serum, still containing blood discs, which A Kohler designates as "ferment-blood" The injection of this ferment blood causes the severe symptoms of ferment intoxication The capillary thromboses and hæmorrhages are largest in the lungs, under the pleura and the pericardium, in the mucous membrane of the small and large intestine, and in the mesenteric and bronchial glands That this ferment intoxication in man, after the transfusion of human blood, is only seen to a limited extent—the initiatory chill of fever, and the dyspnœa and oppression belong here—is due to the fact, as already remarked, that the greater part of the ferment is consumed by the coagulation of the fibrin, which is accelerated by whipping the blood Nevertheless, there are cases in which severe symptoms of intoxication occur, and in which there is nothing wrong with the mode of preparation of the blood In the fatal cases the condition of the heart muscle

[1] Translated by permission of author and publishers, from advance sheets, by Wm G Eggleton M D of Chicago

and of cardiac innervation plays an important part outside of the intoxication, the sudden increase of blood pressure paralyzing the heart, without the occurrence of previous dyspnœa

There is another important point, which has been especially shown by Ponfick and other authors in the transfusion of *heterogeneous* blood all the new blood cells die The hæmoglobin, which is set free by the disintegration of the cells is not excreted by the kidneys merely as indifferent material, but acts on the blood cells of the patient in such a manner as to cause their disintegration, so that by the transfusion of blood of the lower animals into man no active oxygen carriers are added

How is it now regarding the transfusion of homogeneous blood, especially in man? That a slight degree of hæmoglobinuria may occur from homogeneous transfusion cannot be denied, the mechanical insults to which the corpuscles are subjected during defibrination, the overheating of the blood (above 42 C) which easily takes place even in the water bath unless the greatest care be exercised, the presence in the collecting vessels of some of the water which has been used for cleansing them, etc , are all factors which may cause disintegration of numerous blood cells and the setting free of hæmoglobin in the circulating blood Theoretically these things and their consequences are indisputable, but in reality it is different Small quantities of hæmoglobin and large quantities of fibrin ferment can be rendered harmless and eliminated by the blood, probably by the oxygen of the red discs, and we may disregard these apparent dangers But the most certain proof to me that the introduction of defibrinated human blood into the human circulatory system of itself caused no symptoms of hæmoglobinuria and ferment intoxication, is to be found in the complete freedom from reaction after subcutaneous blood injections, if these be made correctly An injection of 200 to 350 ccm of defibrinated blood, a quanty which is completely absorbed, causes neither fever of any consideration nor dyspnœa nor hæmoglobinuria, in short, there are no troubles except the local pain of the injection That in such large quantities many red corpuscles must be destroyed by defibrination, the syringe, the energetic massage, etc , is just as probable as that in spite of defibrination some fibrin ferment must remain It seems that besides the remaining fibrin ferment and the freed hæmoglobin, there must be other factors of danger in intra venous transfusion, as such I consider the mixture of air with the whipped blood, which can never be entirely avoided, the formation of fibrin clots during the injection, and the sudden increase of pressure in the right heart These three factors cause the most alarming symptoms after intra-venous transfusion, and in such a manner that we cannot say in all cases that ferment intoxication is the cause, and the appearance of these symptoms immediately after transfusion is sufficient proof that these three factors are present, and cause the symptoms

One thing, then, is certain, intra venous transfusion may endanger life, and not infrequently does, though we are not clear as to the conditions in individual cases Every one who has often done transfusion or assisted in the operation knows that besides the known causes of danger faults in the technique may easily slip in (such as overheating the blood, mixture with air) if the operation be hurriedly done On account of the hidden dangers and the numerous unfavorable results, this operation has already become to me a very uncomfortable one, and now, since I have found a complete substitute in the method of subcutaneous injections, I would under no circumstances subject a patient to the great dangers of intra venous transfusion Nor can peripheral arterial transfusion, as proposed by Huter, or centripetal arterial transfusion, proposed by von Lesser, be considered as more safe, nor do they recommend themselves to the profession generally

The case is very different when the subcutaneous cellular tissue is selected to receive the blood Here every danger is excluded, as the connective tissue retains the blood clots and particles of air as a fine serve, and by a proper method of injection no blood residuum is produced, or certainly does not lead to phlegmonous inflammation Nor in this case is there any sudden pressure on the right heart, there is no reaction, as from hæmoglobinæmia and ferment intoxication, and as much defibrinated blood or salt water as desired can be inserted in a few minutes, without there being anything of a serious nature in it And this is no small consideration when it is remembered that most transfusions are made after severe hæmorrhage, when the veins are very much narrowed, difficult to find, and it is with difficulty that the cannula can be introduced This loss of time and the dangers are avoided by the subcutaneous method

Bareggi, of Milan, who began to make experiments with subcutaneous blood injections about the same time that I began to study the subject, showed that twelve hours after such an injection (with or without massage?) red corpuscles appeared in the thoracic duct, and that they could be found in the lymph of the thoracic duct three days after the injection was made Bareggi also showed that the red corpuscles could pass in a sound condition through the absorbents of the connective tissue into the lymphatics and through the thoracic duct into the circulation (within twenty minutes after an injection he was able to recognize red blood corpuscles in the large lymphatic trunks of the region in which the injection was made) He also made some experiments on patients, and partly with good results, though his method is not free from faults, as he states that injections of a few up to 50 grams of blood in men were constantly followed by a slight fever His opinion is that blood injections are probably superior to venous and peritoneal transfusion in cases of anæmia running a chronic course, since small injections can be given daily, but that the method cannot displace intra-venous transfusion in cases of acute anæmia

I must decidedly differ with Bareggi as to these conclusions When my method is exactly followed

no fever arises when large quantities of blood are injected at one sitting (100 to 200 ccm), and at most there is only a slight rise of temperature when still larger quantities (250 or 350 ccm) are injected at one sitting Since my first publication on this subject (1885) I have collected a series of new observations which completely bear me out in my assertions I will now describe to you my method of subcutaneous blood injections

After disinfection of the skin at the bend of the elbow the median vein of the donor is opened with a carefully disinfected lancet, and the blood received in a disinfected vessel, carefully dried by means of disinfected mull, being whipped as it flows with a disinfected stick, and finally, after 200 or 300 grams of blood are obtained it is placed in a carefully disinfected beaker glass, on a water bath at a temperature of from 37° to 40° C , and further whipped The water bath should be carefully watched in order that the temperature may not be allowed to rise above 40° C

Meanwhile the patient is prepared for the injections The skin over the anterior, outer and inner portion of the thigh which is the best part of the body for these injections, and when larger quantities are to be injected the legs and arms also, is first washed with a 5 per cent solution of carbolic acid, and then with alcohol, while the patient is chloroformed [1] Chloroform narcosis is absolutely necessary when large quantities are injected, because it alone renders the very painful massage possible My syringes hold exactly 25 grams They are made of glass, with metal protections, and are manufactured very carefully by Katsch, of Munich They are carefully disinfected with carbolized water before the operation, and then washed out with warm distilled water It is not necessary to dry them out after this The cannula is strong and long, and its lumen corresponds very nearly to the second size cannula of Dieulafoy's hollow needle for thoracopuncture With a very narrow cannula the unavoidable fibrin clots cause frequent obstruction, while they are easily forced through a larger one, and without injury to the subcutaneous cellular tissue The cannula is carried through a raised fold of the skin deep into the subcutaneous cellular tissue, and then the syringe is slowly and completely emptied, while an assistant rubs over the point of injection with all his strength This is an important point, it is to prevent an abscess, but the massage must dissipate the blood at the very time that it leaves the cannula The assistant must use borated vaseline freely, and use both hands and all his strength After the cannula is withdrawn massage should be made for a few moments with the flat hand up and down, instead of with full force The duties of the massage assistants are most arduous, the assistants should therefore be changed, as much depends upon their efforts The syringe is now filled again, and an injection made in a new place in the same manner

[1] It is not stated how long the blood must remain on the water bath before being used The supposition is that when the patient is ready the operator should begin immediately but should not remove the blood from the water bath —[*Trans*]

According to the quantity to be injected 6, 8, 10 or more injections must be made, there is no particular limit as to numbers In using 350 grams I once made fourteen injections It makes but little difference whether 100 or 300 grams be injected into the thigh I have generally ceased the injections only when there was no more blood in the beaker glass

Under the powerful massage the subcutaneous cellular tissue must necessarily suffer a good deal of stretching and tearing, which causes pain After the operation, therefore, I have an ice bladder placed over the thigh, and this is renewed as long as the pains continue Ecchymoses are frequent but not invariable results of the injections They most frequently occur in the tender skin on the inner side of the thigh, especially in women The dense adipose tissue of the female is not especially favorable for subcutaneous injections The meshes of the subcutaneous cellular tissue are everywhere filled with fat cells, and on this account there is great resistance to the dissipation and absorption of the injected blood In order to study these difficulties closely, I have made a large number of injections in female cases, and it is apparent that the female sex offers the greater number of cases requiring the operation But in spite of the density of the adipose tissue in the female the injected blood may be completely dissipated After injections in persons practically under sentence of death, I have examined the condition of the adipose tissue on the cadaver a few days after the injections were made Nothing abnormal was found besides slight hæmorrhagic imbibition of the fatty cellular tissue, and nothing of imbibition was found when death took place a few weeks or months after the injections were made

It is very important that the needle be carried as deeply as possible after the adipose tissue has been taken up in a thick fold, and the injection should be made slowly so that the blood may be completely dissipated by the massage When the precautions mentioned are carried out inflammation and suppuration will not occur When small quantities are injected (from 50 to 100 grams) the pain after the injections is very slight, and the patient can use the leg again in two or three days But with larger quantities the pain is considerable and more lasting, and the patient has to keep his bed for five or six days Of the large number of injections which I have made in the last few years, I have seen inflammation and suppuration in only two cases, and in both they were due to avoidable faults in the technique Hæmoglobinuria never occurs, and very seldom respiratory and digestive troubles

The favorable results of blood injections are transitory and permanent First of all the increase in the amount of hæmoglobin in the blood must be determined The increase does not always correspond to the quantity of blood injected, and is so much the more noticeable as the hæmoglobin was low before the injection The amount of hæmoglobin is determined spectroscopically, which is thus far the most certain and exact method The hæmochromometers of Bizzozero and von Fleischl, which I

have often used for comparison, will come into more general use, as there is a pressing need of an uncomplicated and inexpensive apparatus for the determination of hæmoglobin Not until hæmoglobin can be determined without minute details and loss of time will the value of this physiological factor become apparent for the diagnosis, prognosis and treatment of many diseases The splendid work of Leichtenstern shows us what a mine of interesting and important facts bearing on this subject there is to be worked [2]

All the hæmoglobin determinations in our clinical institute have been made by Vierordt's method, as recommended by Leichtenstern [3] The spectroscope and all apparatus was made by Steinheil The collection and mixing of the blood is done at the bed side, or directly by the apparatus if the patient can leave the bed The dilution is generally 1 200, and 1 100 only in high degrees of oligochromæmia The light power in each case was determined from the mean of 10 observations, and from this the extinction coefficient was calculated The observations should always be made between 10 and 12 in the forenoon, and 6 and 8 in the afternoon, so that they may not be affected by the daily variation or by the ingestion of food The daily variation in the hæmoglobin, which Leichtenstern found in healthy persons, takes place principally at noon and midnight, being higher between 12 and 2, and lower between 4 and 6 than the average By making the observations at the times indicated the influence of these variations is avoided We may leave out of consideration the somewhat higher proportion of hæmoglobin in the male sex, since as a rule all that we want is the relative amount of hæmoglobin

One or more estimates of hæmoglobin should be made before the injection is made After the injection the first estimate should be made within twenty-four hours, in order to see the primary effect of the operation, and then again in one or two days to determine the decrease after the increase In many cases also the blood corpuscles should be counted (Zeiss's apparatus)[4], as this may be of more value in judging of the blood gain than the estimation of the hæmoglobin Of course the amount of color is not always parallel with the number of corpuscles, indeed, it may reach a comparatively high mark, while there is a relatively slight decrease in the number of corpuscles On the other hand, a comparatively slight oligochromæmia may exist at the same time with a relatively considerable oligocythæmia To illustrate this I will give a few examples of the different proportions of hæmoglobin to corpuscles in different affections From the authors named above I take as the normal for the corpuscles, 5,000,000 per cubic centimetre, for the hæmoglobin, 1 4400= extinction coefficient [5]

1 C K, male, æt 22 Plethora universalis, polycythæmia Hypochondriac Food very richly albuminous, frequent epistaxis, palpitations of heart, congestions, some enlargement of spleen, has taken much iron in last few months Corpuscles 6,200,000 in ccm, hæmoglobin 111 24 per cent After two months of dieting (reduction of albuminoids, riding, mountain climbing) corpuscles 5,600,000 in ccm, hæmoglobin 102 17 per cent

2 D L, male, æt 18 Pseudo-leukæmia (splenic tumor 24×10), oligocythæmia proportionately higher than the oligochromæmia Corpuscles 3,325,000 in ccm, proportion of white to red, 1 316, hæmoglobin, 67 79 per cent

3 C W, female, æt 24 Malarial cachexia, high degree of oligochromæmia, comparatively slight oligocythæmia Corpuscles 4,600,000 in ccm, proportion of white to red, 1 229, hæmoglobin, 24 15 per cent

4 A B female, æt 15 Chlorosis, oligochromæmia marked, oligocythæmia of less degree Corpuscles, 3,500,000, hæmoglobin, 32 40 per cent

5 W B, female, æt 24 Ulcer of stomach, anæmia, oligochromæmia and oligocythæmia tolerably equally and well marked Coloring matter and corpuscles each less than one half normal Corpuscles 2,217,500, white to red, 1 265, hæmoglobin, 34 86 per cent

These examples serve to show the variability of the two factors, and of their proportions to each other This is not the place to say more of this special part of the subject, but those who are interested can consult the works of Gessler and Graeber

The increase of hæmoglobin is greatest within the first twenty-four hours after the injection, and it then gradually falls during the next few days As a rule there remains an excess above the quantity present before the injection, though there are cases of severe anæmia, from different causes, in which the *status quo ante injectionem* is reached again in a few days After a longer or shorter interval repeated injections may gradually increase the amount of the iron in the hæmoglobin, though the primary increase and secondary decrease of the hæmoglobin is repeated after each injection The larger the injection of course the greater is the up and down variation The following will illustrate very clearly what has been said

R C, female, æt 23 Severe chlorosis, with gastric troubles Iron and generous diet from Nov 26 until Jan 8 almost with out the slightest good result

Nov 26,	6 P M,	hæmoglobin	23 26 per cent
Dec 7,	"	"	24 33 "
" 8,	10 A M	"	24 60 "
" 8,	10 30 A M,	injection of 200 ccm defibrinated human blood	

[2] Leichtenstern Untersuchungen uber den Hæmoglobingehalt des Blutes in gesunden und kranken Zuständen Leipsig F C W Vogel

[3] Vierordt's method, while possibly more accurate than the estimation of hæmoglobin by von Fleischl's or Gower's hæmometer entails a large amount of trouble, and unless one can use a spectroscope, and has one at his disposal, it is impracticable The hæmometers of von Fleischl and Gowers are simple, determining the amount of hæmoglobin in the one case by a ruby colored wedge of glass, and in the second case by comparison with some standard solution, as picrocarminate of ammonia —[*Trans*]

[4] This is an apparatus composed of the pipette used with Malassez' "compte globules," known as the mixer of Potain, and a cell similar to that of Gower's The squares in Zeiss's hæmacytometer are only 1 20 millimetre, which renders the counting easy It may be used with any microscope without adjustment for the different objectives —[*Trans*]

[5] 1 4400 represents normal amount of hæmoglobin, or 100 per cent The extinction coefficient is calculated from the amount of light shut off in passing through the hæmoglobin solution In his lecture Professor Ziemssen only gives the extinction coefficient in each case, but not the percentage of hæmoglobin which it represents—which is unintelligible to one who does not understand the method In this translation the per centage has been calculated, though as a rule only two decimals are given —[*Trans*]

Dec 9, 10 30 A M, hæmoglobin 42 21 per cent
" 10, 10 00 A M, " 35 91 "
" 13, 5 30 P M, " 28 83 "
" 15, 5 00 P M, " 30 001 "
" 16, 10 00 A M, " 20 42 "
" 16, 10 30 A M, injection of 100 ccm human blood
" 17, 6 00 P M, hæmoglobin 38 52 per cent
" 18, 7 00 P M, " 32 34 "
Jan 7, 7 00 A M, " 32 85 "
" 7, 11 30 A M, injection of 275 ccm human blood
" 9, 5 00 P M, hæmoglobin 64 54 per cent
" 19, 10 00 A M, " 44 002 "

It is interesting in this case to see how little the iron and generous diet did to increase the amount of the hæmoglobin The separate injections of 200, 100, and 275 ccm, on Dec 7 and 16, and Jan 7, caused not only a considerable primary increase of the amount of the hæmoglobin, corresponding to the amount of blood injected, but also a secondary and gradually increasing quantity of iron in the hæmoglobin The increased amount of blood given to the system was also considerable At the last operation 275 ccm, or $\frac{1}{21}$ of the body weight, was injected, and within twenty four days 575 ccm, or $\frac{1}{10\frac{1}{4}}$ of the body-weight Very striking was the improved color of the skin and mucous membranes after each injection, being in direct proportion to the amount of blood injected, and to the degree of existing oligochromæmia By this bettered condition of the color the general appearance of the face was markedly changed from day to day This was especially apparent after the last injection, which was followed by not the slightest general disturbance, by no fever, and by no abnormality of the urine This improved condition of color was also marked in a case which I saw with Dr Benczur, the case being that of an extremely anæmic little girl of 8 years In this case 50 ccm of blood were injected into the thigh On the next day the hæmoglobin had risen from 16 11 to 30 64 per cent There was no fever or other trouble In this case the injection amounted to $\frac{1}{38\frac{1}{2}}$ of the body-weight, or $\frac{1}{3\frac{1}{2}}$ of the whole mass of blood, as Bischoff states that the blood mass is $\frac{1}{11}$ the weight of the body But in the other case it will be seen that the injections amounted to $\frac{1}{10}$ the presumptive blood-mass

With the improved color of the skin and mucous membranes is an increased freshness of appearance, increased muscular energy, and better appetite and sleep Of course these secondary results are not always equally developed First of all, the secondary effects always depend on the nature of the trouble, and on the amount of blood injected, and the duration of the improvement of the general functions varies very much with these In many cases only one injection is necessary, in others more

What we can attain therapeutically in this way, of what value subcutaneous blood injections are in individual diseases, which require renewal or increase of blood, we cannot tell at the present time But it is sufficiently demonstrated to me that subcutaneous blood injections can be used without difficulty or danger to the patient, that a considerable quantity of blood may be used without endangering the safety of the patient, that the favorable results thus far shown are probably permanent, and that there is not only an increase in the fluid quantity of the blood, but an actual transplantation of blood cells By further experiments we must distinguish between the primary, and the secondary or permanent, effects, we will then have to differentiate in regard to the primary effects, which of them are to be attributed only to the increased quantity of fluid blood, and which to the supply of functionating oxygen carriers

(To be concluded)

THE AFTER-TREATMENT OF CATARACT CASES, TO THE EXCLUSION OF COMPRESSES, BANDAGES, DARK ROOMS AND RESTRAINT

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association

BY JULIAN J CHISOLM, M D,

SURGEON IN CHARGE OF THE PRESBYTERIAN EYE AND EAR CHARITY HOSPITAL, BALTIMORE, MD

At the last meeting of the American Medical Association, May, 1886, in St Louis, I reported to the Section on Ophthalmology that Dr Charles Michel, of St Louis, was treating cataract cases in light rooms with adhesive straps, instead of by compresses and bandages in dark rooms, and that he found it a desirable method of treatment Although the discussion which followed showed clearly that the members of the Section did not endorse the method, or think well of it, yet I was so impressed by it, that I told the Section that I would at once test this plan of treatment and would report at the ensuing meeting in Chicago the results of my experiments Having control of all the material at the Presbyterian Hospital of Baltimore City, to which last year were drawn, among its 6,125 cases, 342 cases of lens troubles, I had ample opportunity, immediately upon my return from St Louis, to put the suggested method into practice

During the month of May, 1886, sixteen cataract extractions, beside iridectomies, were dressed with a strip of isinglass plaster as the sole dressing, and were kept in moderately lighted rooms These plasters were put on each eye, and were removed on the fifth day After removal the eyes, by contrast with those treated by bandages and in the dark, were found less red, with less lachrymation, and less photophobia Moreover, convalescence seemed to be expedited to the extent that cataract patients, at the end of two weeks, could enjoy the freedom of the entire house without smoked glasses and without inconvenience

Upon further experimentation, I found that much of the restraint practised by Dr Michel and by other ophthalmic surgeons, such as keeping the patients on their backs in bed for a number of days, with both eyes closed, was unnecessary As I eliminated them one after another I found that they had not added to the per cent of successes, and certainly not to the comfort of the patient I now feel that I have settled down upon a method of treating cataract cases after

operation which is far in advance of the accepted after-treatment in general use My cataract extractions since May 12, 1886, number ninety eight, and my iridectomies sixty seven, an experience amply large to test the efficacy of any one particular method I now can say, without reserve, that I have abandoned absolutely compresses, bandages, dark rooms and restraints from the after-treatment of cataract cases, and that my per cent of good results exceeds my former experience under the old methods of compresses, bandages and dark rooms still too general in use, to the annoyance of both surgeon and patient

My method of procedure is as follows Patients are operated upon, as a rule, upon the day they present themselves for treatment, if they feel well and do not complain of fatigue from travel They undergo no preparation whatever My experience is that healthy patients, requiring operations on their eyes for the restoration of sight, do best when their systems are not disturbed by medication, and are also better off when not kept in suspense by deferred operations In cataract operations particularly, they cannot disassociate from this sensitive organ, the eye, a painful operative procedure It is a great relief to all of them to have the trying ordeal over, and with it the cause for a very disturbing nervous excitement is removed I have no superstitions concerning the necessity for daily evacuations of the bowels, which haunt the minds and guide the practice of so many physicians Should complaint of constipation, and fulness of the head as a consequence, be made prior to the operation or during the course of treatment, a purgative is given, but it is the exception, not the rule

All cases are operated upon in the operating room of the hospital, on a table of suitable height and width, which stands in a projection containing three very large windows, so that I have ample light to operate on cloudy as well as on bright days Considering the operation itself as by far the most important part of the entire treatment for the restoration of good vision, in eye cases, and that, when the operation is well done, nine tenths of the battle is gained, I try to secure every convenience for both patient and surgeon during this very important crisis After full trial I have abandoned operating upon patients in their beds Too much inconvenience is occasioned from the awkward positions and body contortions of the surgeon during these bed manipulations Unless the surgeon is perfectly at his ease, and has perfect control of the head of the patient, he cannot do the important manual work with satisfaction

I have never seen any trouble come from the movements of the body after the eye was properly dressed I do contrast most favorably the quiet walking of a patient from the table to his room after a cocaine extraction as against the violent retching from the general anæsthetic of a few years since, in bed operations, and yet we know that these violent convulsive acts were not incompatible with the most perfect results in restored vision to cataract patients

The table I use is narrow, facilitating manipulation from the head or from either side, and is just so high as to permit me to stand while operating, without uncomfortably bending I have sixteen private rooms connected with the Presbyterian Eye and Ear Charity Hospital, and I succeed in inducing most of my private patients needing operations to use them, therefore I am never called upon to operate in hotels or private boarding houses, and if I can help it, not in private dwellings, so that, in by far the majority of my cataract cases, I can enjoy the comfort of my hospital operating room and the operating table

In cataract cases I use invariably a 4 per cent solution of the muriate of cocaine for local anæsthesia I have used it now in nearly 300 cataract extractions, and have reason to extol its peculiar advantages for eye surgery I have never seen harm come from its use, and have every confidence in its efficacy and safety It is instilled into the eye when the patient reaches the operating room, and most frequently when he is on the operating table Usually, in five minutes the eye is fully anæsthetized, and is then ready for operation After the speculum is inserted the eye is suffused with a biniodide of mercury solution, 1 part to 20,000 By elevating the speculum the antiseptic solution is brought into contact with every part of the mucous lining of the lids and eyeball, and is much more thoroughly applied than when the everted lids are mopped as I have seen done by others If there be any virtue in the use of the germicide, it is all-important that no septic germs be left hid away in folds of membrane The wiping of lids and cornea cannot make a complete application for thorough cleansing Before using any of the instruments they are put under the hot water spout They are also washed with very hot water as soon as they are used In this way cleanliness is ensured

I make a wound in the clear cornea near the scleral border, large enough to allow of the free exit of the lens I make a small iridectomy, taking care, however, that no portion of the iris remains caught in the angle of the wound When the iris is drawn out by the forceps, one clip of the scissors removes all that is needful for the iridectomy Blood in the anterior chamber from the section of the iris I see much less frequently than in former years, and this I attribute to the constringing effects of cocaine on the iritic vessels, as evinced before the corneal section by the dilatation of the pupil I have made five extractions recently without iridectomy, but have not succeeded in getting a perfect pupil in any of them, all the cases had some iritic inflammation, enough to make the pupil dilate irregularly under atropia In two cases there were small iritic herniæ, although eserine had been freely used Notwithstanding the fact that I lost none of these eyes, I have resumed iridectomy as the less hazardous method

The capsule is opened freely, usually by horizontal incision over the upper margin of the lens, although sometimes I make the capsulotomy boldly over the pupillary face of the lens The lens, with all detritus, is removed by pressure of the rubber spoon upon the face of the cornea, making pressure with the edge of a second spoon upon the scleral border of the wound to dislodge particles of lens substance which may be caught under this ledge Should any cloud-

ing exist in the capsule, rendering it visible after the lens has escaped, I introduce the iris forceps and extract the capsule entire This always leaves a perfectly black pupil, and ensures a perfect result When the operation is finished and before the speculum is removed, the surface of the eye is again flooded with the antiseptic bimiodide of mercury liquid When this runs away by tilting the head sideways, the speculum is removed

After testing the vision in finger counting, the eyes are closed The outer surface of the lids of the eye operated upon is wiped dry of the excess of the bin iodide solution which had covered them I now take a piece of very thin, diaphanous white silk isinglass plaster 1½ inch long and 1 inch wide, moisten this with the antiseptic solution, and lay it over the closed lids of the eye operated upon It extends from just under the eyebrow to the cheek and is wide enough to nearly cover the palpebral split, leaving the great angle beyond the puncta exposed for the escape of eye secretions, and also for the admission of atropia drops by capillary action, without disturbing the strap, should such drops be needed during the after treatment In its wet, softened and flaccid condition, the adhesive strap can be stroked by the spoon until every crease is effaced, and every eyelash, as seen through the strap, lies down smoothly upon the cheek This pressure of the spoon is continued till the isinglass plaster adheres firmly at every point and becomes dry I use the thin silk plaster in preference to the gold beater's skin, as suggested by Dr Michel, because it has more body and wears better Usually the one piece remains on for the five days needful for the firm corneal healing, and does not need replacing When using the gold beater's skin I found that, on more than one occasion, the action of the lid muscles had ruptured the film When this occurred on the third day it was not so objectionable, but when on the first day, before the corneal wound had healed, it was deemed an accident which could be prevented by using a stronger material When the plaster is dry the two lids are made, as it were, one, with such perfect support of the eyeball that there is no fear whatever of disturbing the wound by any movement of the head or body I now allow the patient to open his other eye, get down from the operating table and, if he has sight enough in the open eye to guide himself, walk to his room without assistance, after descending two flights of stairs in doing so

Every window in the hospital, chambers, halls and water closets, has blue shades, which keep out the sun, leaving the house pleasantly lighted When the patient reaches his chamber he may go to bed or not, as he pleases Usually they prefer to lay on the bed dressed, and not take off their clothes till bedtime My experience in the past year proves that patients do best who are least trammeled, therefore I give no orders about their movements, positions or diet, except to restrict them to their rooms for a few days, and prohibit the use of the opened eye for reading They may remain in or out of bed, as they feel disposed, dressing and undressing themselves If both eyes are not cataractous, they can see to eat with the opened eye, and enjoy their meals They are allowed to see friends, and have the days of confinement to their rooms pass as pleasantly as possible By means of this open eye they can take as good care of themselves as they did the day before the operation The patient is restricted from using the eye in reading only, and finds it of immense comfort in dressing, walking, and eating By this method of treatment very little nursing is required

Often the patient has no pain whatever during the operation or afterwards, the entire convalescence being absolutely a painless one Some, on the contrary, complain of pain in the eye during the first night after operation Should this night pain be sharp and make the patient nervous, a drop of a 1 per cent solution of atropia, put at the inner canthus, is sucked in between the lids and usually soothes promptly Rarely is it found necessary to administer morphine to allay this pain If the patient is nervous at bedtime and fears a sleepless night, a dose of the bromides with chloral is administered The use of this chloral mixture is the exception

When I visit the patients the day after the operation, I usually find them dressed, sometimes lying on the bed, or reclining on a lounge, sitting in a rocking-chair or walking the room for exercise They feel comfortable, have had their usual meals, and, if regular in habits, the morning call of nature By the light of the room (for no candles are needed for inspection), the plaster strap on the closed eye is seen a little wrinkled, and shows evidence of having been moist at the lid split The escaped secretions of the night have dried upon the strap and were not in sufficient quantity to disturb the adjustment or detach the plaster from the lid surface Through the transparent strap the lids are seen in their normal condition, no redness, nor swelling, nor mattering along the visible row of lashes The visit is designed for inspection only, for no dressing nor treatment of any kind is needed, and the isinglass strap is not disturbed The second, third and fourth days are usually duplicates of the first The patient has had no pain or inconvenience He has carried out pretty much his ordinary habits of life After a good night s sleep he has risen at his usual hour, dressed himself, washed his face, avoiding wetting the plaster by using the wetted end of a towel, eats his three regular meals without restriction as to articles of diet, has received the visits of his friends, and has been read to between times to make time pass more agreeably, the light of the room being sufficient to allow this The straps have been examined each day to observe their condition, but more especially to note the appearance of the lids and the condition of discharges which have dried upon the plaster The strap may show more wrinkles, but usually has remained firmly adherent. If found at any time loose it is removed, and a second adjusted Not once in ten cases is it necessary to renew the strap applied the day of operation

On the fifth day, the corneal wound having firmly healed and the strap having accomplished its work, it is removed by wetting it The liberated lids separate, and the restored sight to the eye is recognized at once by the patient The light of the room hav-

ing been sufficient at any time to inspect the condition of the lids, is also sufficient to allow of the inspection of the eye itself To those accustomed to examine eyes successfully operated upon for cataract extraction by candle-light, five days after the operation has been performed, when treated by compresses and bandages in dark rooms, one is at once struck by the absence of redness, weeping and sensitiveness to light which are the constant companions of the former treatment The patient feels a little moisture as the eye is first opened, but the surgeon does not see the tears coursing down the cheek as when the thick compresses are first removed With the removal of the isinglass strap no change is made in the daily life of the patient, or in his surroundings No smoked glasses nor eye screens are used, nor is the light of the room in any way diminished For two or three days longer he is restricted to the room, a little more light being daily admitted by drawing aside the window shade By the eighth day the patient is allowed the freedom of the house, and can go into any room from which the sunlight is excluded By the tenth day I have often found them with raised curtain looking into the sunny street, but this was a liberty which they alone were responsible for It was not advised, and yet no trouble came of it in any case At this stage of the convalescence the ordinary light of a living room is not offensive to the eye recently operated upon By the fourteenth day the patient is ready for discharge from treatment, having a strong eye, and often so little injected as scarcely to be recognizable from the one not operated upon For two weeks after dismissal I usually advise a smoked glass for the sunny street, but none for home use I have often found this advice disregarded, patients finding no inconvenience for street exposure and without the protection of smoked glasses Should they have them on, I find them looking over the rims, which means that the eye is standing all the exposure as if no glass was worn

In operating on patients at their own dwellings, they are never put to bed With one eye open they are able to exercise themselves by walking about their chamber By the seventh day they are down stairs in the shaded parlor, and are allowed to take their meals with the family, the dining room window curtains being lowered

This method of treating cataract extractions has been under my close observation for twelve months The method of leaving one eye open for guidance has been continuously used for four months, and in not a single case have I seen any harm whatever come of it My cataract and iridectomy cases treated by the isinglass plaster dressing number 167 With me it is no longer a subject of experimentation It has settled down with me as the regular method of treating such cases, and I now use no other I can truly say that bed operations, compresses and bandages, dark rooms, bed treatment, diet and restraints of all kinds, are no longer in use by me in eye practice My greater per cent of successes, to say nothing of the inestimable comfort to the patient, warrants me in the statement that I would be doing injury as well as injustice to my patients, should I go back to the old methods of after-treatment in constant use by me prior to May, 1886

This method of treating cataract and iridectomy cases, revolutionary as it seems, carries reasonableness on its very face An eye accustomed to strong light is not inconvenienced by it, and a healthy eye kept for a short time in darkness may soon acquire a sensitiveness which makes strong light annoying Everybody has had personal experience of this, when sitting at twilight in a room and the gas is suddenly lighted Cataract patients, under the long continued darkness of compresses and bandages, experience this the more especially, hence, under the treatment of seclusion generally in vogue, congested, watery, and sensitive eyes, the one not operated upon as well as the one operated upon, had to be, and must ever be, for such is the law of nature The reverse is equally the law of nature, and my everyday experience proves it Do not exclude light from cataract eyes and they will not be annoyed by it *In other words, the congestion, photophobia and lachrymation so constantly found in eyes recently operated upon for cataract extraction, when the heavy, thick bandages are removed are caused by the dressing, and are not a natural sequence of the operation* Change the dressings to the light ones and the irritation of the eyes will diminish to a wonderful extent

As to the diaphanous adhesive strap, it is infinitely preferable to the compress and bandage on account of admitting light to the eye, and also in its more perfect adjustment We will all acknowledge that after a cataract extraction, when we say to the patient, "the operation is now finished, close your eyes," that we believe that the lips of the corneal wound are adjusted and in proper condition for quick union All that any surgeon can wish for is to keep them so, and the closed lids are doing it Keep the lids closed and the desirable effects are insured Now, what is the best means of doing this? Is it by putting a piece of clean linen on the closed eyes, then a compress of cotton, well secured to the eye by a head bandage, or by using a light piece of isinglass plaster which really has no appreciable weight, and yet sticks to the skin as if it were a part of it, glueing the lashes to the cheek and making of the two lids one piece, to the perfect and permanent support of the front of the eyeball? Personal experience on the part of patients endorses the latter method I have patients who at intervals of two years have had cataract extractions made The first one was under compresses, in dark rooms and with restraint in bed, the second by an adhesive strip for one eye only, in a light room, and without any interference with their movements As by both methods they secured good sight, they are loud in their praises of the adhesive strap method, and look back with dread to the eight days of continuous night to them

The front of the eye is the prominent part of an elastic ball When pressure is made upon it, the prominence must be pressed in and the equator of the ball necessarily bulged out When the eye has been cut open near the line of the equator, as in corneal section for cataract, any pressure upon the eyeball by a well secured compress must tend to displace

the base line and disturb the nice adjustment of the lips of the corneal incision which the closed lids had effected If the compresses are not snugly secured by the bandages surrounding the head, then they do not interfere with the lid support, and are simply a useless incumbrance, annoying the patient by their weight, and their presence As the patient, under this dressing, is kept in bed, every movement of the head pulls more or less unequally upon the bandage, and must cause irregular pressure upon the cut eye ball, to its annoyance To keep up by the bandage just such a degree of support as not to cause more or less pressure, is more difficult than at first glance would appear The varied movements of the patient's head upon the pillow, with irregular drawing upon the head band, can never be taken into account, and yet they make an all important factor during the early days of treatment

The removal daily of the bandages for eye inspection, and the reapplication of a fresh dressing, is considered very comfortable to the patient, and the reason for his gratitude is apparent When a loose mass of elastic cotton is used as the compress—and it is by far the best—it is always found converted into a cake by the twenty four hours' wearing, and its natural elasticity is gone This is more especially the case when water applications are made This matted condition of the cotton compress is an indication of the extent that the eye has been squeezed by the head movements, for the cakey pad did not exist when the patient was put to bed The daily inspection of the lids, making removal of the compresses and their readjustment necessary, is agreeable to the patient for two reasons first, in replacing the cotton cake by a fresh, elastic piece, the patient gets rid of some of the irregular pressure which his night movements had occasioned, and secondly, he gets a glimpse of the daylight and a ray of hope for future sight—an inestimable reassuring comfort to one who has been confined to utter darkness for twenty-four hours

With the light adhesive strap the pressure must ever be just what nature intended The tarsal cartilages, which during a long life had been moulded by nature for the very purpose of fitting, by their smooth concavity, every point of corneal convexity, and thereby give absolute and perfect support, are kept in position as in sleep without pressure, by the tonic contraction of the palpebral muscle The adhesive strap, when properly applied, keeps the lid closed, and by so doing keeps up a permanent tonic contraction of the palpebral muscle It therefore becomes a perfect retaining and sustaining dressing

When this strap has dried on the lid, and had been properly adjusted, the eyeball is safe from accident No ordinary movement imparted to the body can affect it, and therefore confinement to bed, with all kind of restraints, becomes needless Under the general anæsthetics in former use in eye operations, with the retching and vomiting daily experienced, the light adhesive strap might have been deemed hazardous, and yet, when an eye dressed by the isinglass plaster is inspected, the thorough support given by the eyelid to the front of the eyeball would reassure any observer that it is a far better protection than the compress and bandages, and that the corneal wound cannot be influenced by any movements of the jaws or legs Hence it is that the experience of the past year has taught me that restrictions in eating, talking and walking do not influence the good results attained Therefore, to keep patients immovable in bed on their backs, fed on slops, and not allowed to converse, is an arbitrary exhibition of professional authority

Extract from an article on the "After Treatment of Cataract Operations," by Dr C Michel, in the September number of the *Archives of Ophthalmology*, 1886 "On the fourth or fifth day the patient is allowed to turn on the unoperated side, to relieve the aching produced by the dorsal decubitus, and from the sixth to the eighth day he is bolstered up in a sitting posture in bed, and the eye not operated upon left open From the ninth or tenth day the operated eye is no longer closed, and the patient is dressed and permitted to leave the bed for a chair "

For the last six months I have not put patients to bed at all, and leave the choice of bed, chair or lounge to themselves If they desire to go to bed, I do not object If they prefer to go to a lounge from the operating table and remain dressed until their usual bedtime, I equally do not object So confident am I that the eye well strapped cannot be disturbed by any ordinary movements of the patients, I place no restrictions in their way I can easily imagine the horror of the unmitiated, when they see my male patients pulling their day shirt over their heads the night after the operation, to replace it by the more easy fitting night shirt, and dressing again in the early morning When, after watching this most unusual proceeding for five consecutive days, hearing no complaints of pain or uneasiness, nor evidence of lid redness, or eye mattering, the adhesive strip is removed by wetting it—for it still holds on as if it were a part of the skin itself—the eye opens widely, with no weeping and but little injection, and bearing the exposure to the moderate light of the room for inspection without discomfort, his horror at first and subsequent surprise give way to admiration at the beautiful results in the absence of restraint

I do not know who invented the theory that the movements of the jaw, as in chewing, will impart dangerous movements to the corneal wound, and therefore should not be indulged in by patients recently operated upon for cataract Possibly movements of the temporal muscles may be transmitted to the head bandages and from them to the compresses The moment the bands encircling the head are omitted, the eyes are isolated from jaw movements The starvation of patients during the early days of a cataract operation, under the isinglass dressing, becomes unnecessary

The use of the adhesive strap and treatment in light rooms, as suggested to me by Dr Michel, was an immense improvement over the compress and dark rooms treatment Another great advance was made by me when I was enabled to eliminate, step by step, the bed operation, the bed treatment, and the diet list

The crowning work of my past year's experiences was when I freed the good eye from the bandage This was a bold step, and was undertaken with a great deal of anxiety I assumed that if iridectomies could be treated by bandaging only the eye operated upon, as my ample experience had already proved, cataract extractions might be similarly cared for

My first case was tried on February 18, 1887 The patient, a male, aged 50, in good health, had been myopic all his life In the right eye he had been getting blind for five years with cataract, now fully ripe In the left eye there were small marginal lens striations An ophthalmoscopic examination showed a very large irregular crescent of choroidal atrophy around the disc With a $\frac{1}{12}$ lens he had $\frac{1}{50}$ vision The cataract extraction, under cocaine, on the operating table, in the operating room of the Presbyterian Hospital, was smooth Only this eye was closed by an isinglass plaster strap, carefully adjusted The other eye was left undisturbed, enjoying all the vision he had before the operation He got down from the operating table, and without assistance walked up stairs into the ward, and was not put to bed As far as he individually was concerned he could appreciate no difference in his condition between the day before and the day after operation For the past five years he had had but one good eye for use, and he continued to use it as heretofore On my visit to the hospital the day after the operation, I found him walking about the ward He had retired with the other patients, and had also gotten up with them, and had all the privileges which the other inmates of the ward were enjoying. On the fifth day, a period which experience has taught me that protection was no longer necessary, I removed the adhesive strap By the tenth day I found him with other patients looking out of the window into the sunny street the blue curtain of the ward window having been drawn aside He was detained in the hospital longer than usual, seventeen days, because I considered him a case of unusual interest He went out without smoked glasses, deeming them unnecessary With $\frac{1}{12}$ + the vision in this eye was $\frac{20}{40}$, quite as good as in the eye not operated upon On ophthalmoscopic examination the eye from which the cataract was removed indicated also a large cresent with choroidal atrophy around the disc

This most satisfactory conduct of this patient's eye was an incentive for further trial of this new and revolutionary practice On February 23 the second case of cataract extraction was submitted to the same treatment, and on February 28 the third case As all of these did well, and seemed in no way injuriously affected by the great latitude allowed, it became from that time my established method of treatment Now all my cataract patients have the inestimable comfort of having an eye for their guidance during the treatment for cataract extraction This great privilege, with the freedom of their moderately lighted chambers and the simple transparent, light, permanent dressing, with no bed treatment, marks an era in eye surgery that cannot be too highly estimated From my present experience I can clearly see how the congested, watery, sensitive eyes, so constantly met with after the bandages have been removed in the ordinary method of dressing eyes after cataract extractions as to be considered a proper part in the convalescence, are clearly traceable to the restraining treatment It is the heavy bandages with the dark rooms that does it, because when I do not use the compresses, and keep my patients in light rooms, I do not see these complications, antagonistic to rapid convalescence In former years the Presbyterian Eye Hospital bought smoked glasses by the gross, and every iridectomy and cataract patient was supplied with them as soon as the bandages were removed Now there is not one worn in the hospital, and very few patients see the necessity of putting them on when they leave the house

The year's experimental work undertaken at the Presbyterian Eye and Ear Charity Hospital of Baltimore has shown conclusively that a cataract patient not submitted to darkness, but with eyes bearing the light throughout the entire treatment, will have strong ones when the strap is removed on the fifth day A very extensive experience of former years has also conclusively shown that if I keep an eye in the dark for even a few days, I will have one which must run water and show congestion when the light is admitted to it If an eye is strong when both eyes are only lightly covered, the eye operated upon will be stronger if only one eye be covered, and the good eye be permitted to enjoy its accustomed stimulus (light) undisturbed

If only as good results are secured by this rational treatment, over the method of compresses, bandages, dark rooms and restraints of all kinds, then why should not patients enjoy the comforts of the one when contrasted with the annoyances of the other?

My experiences of the past year show conclusively that not only is the patient made more comfortable by the plan suggested, but that a larger per cent of good results can be secured Of course there are certain unfavorable results at times obtained which no care can prevent No one should look for absolute success in every case Failures will now and then come to the most skilful Of the sixty seven iridectomies I lost none Of the ninety eight cataract extractions I lost five eyes

Case 1 —Mrs A , aged 71, extremely myopic, cataract well matured in the left eye Operation smooth Had some pains during treatment Left the hospital with good vision Some days after dismissal plastic iritis ensued, and the eye was finally lost Mrs A was in poor health, and was in deep grief from the recent loss of her husband I do not know whether the return to her home, with its sad memories, had anything to do with the subsequent inflammation This I count, however, as one of my losses

Case 2 —Mr R , aged 92, an old, feeble man Iritis came on during treatment, and the eye was lost

Case 3 —Mr B , aged 39, has had diabetes mellitus for years, and passes over a gallon of urine per day, loaded with sugar Has lost much flesh Cataract matured in each eye Left eye operated upon with restored vision, a perfect result, $V = \frac{20}{20}$ Three weeks afterwards right eye operated upon Inflammation ensued and this eye was lost

Case 4—Mr B, aged 65, cataract in each eye Much depressed in spirits, thought himself well off financially, but has recently been beggared Cataract fully formed in the left eye, still sees to get about with the right eye Cataract extraction smooth Eye pained from the first night, necessitating the liberal administration of opium During the day there was not much suffering, it always appeared aggravated at night The lid at no time red, nor any escaping secretions The strap was removed on the fifth day Cornea clear, eye injected, pupil free and fully dilated under atropia, which had been daily instilled Lymph masses seen in the vitreous Hyalitis had established itself which eventually destroyed the eye

Case 5—Mrs B, at 74, in very feeble health, cataract fully formed in the right eye for six months, has vision enough to get about with the left eye Lens extraction under cocaine smooth Commenced to suffer pain soon after the operation Lids commenced to swell by the third day, and the eye was lost by panophthalmitis A few days before she was operated upon four boys, aged from 10 to 14 years, were received from an industrial reformatory school All had purulent conjunctivitis with corneal ulceration and large iritic hernie Septic germs were found in abundance in the eye secretions from the eyes of these boys, and three had to have iridectomies to save the cornea from general sloughing By some oversight or careless manipulation this case seemed to me one of contagion

Case 6—Mrs K, aged 62, of a very nervous temperament, had a cataract fully formed in the left eye, and forming in the right eye Her everyday life was a very unhappy one, full of care and trouble She was the second wife of an old man of 80 nearly an imbecile, with a number of grown step children living in the house who were always making trouble Crying spells were of frequent occurrence during her treatment She had iritis which has thoroughly shut up her pupil She has a clear cornea and good light perception, so that there is a promise that this case can have sight restored by an iridectomy

If these cases be carefully analyzed, it may be considered an open question whether these eyes could have been saved under any method of treatment Call them all however legitimate losses, and they still make an excellent showing for the proposed method of treating cataract eyes after extraction operations, 92 useful eyes out of 98 extractions, is satisfactory eye surgery, and is not often excelled

This method of treating cataract and iridectomy cases after operation has given me great satisfaction The isinglass plasters and light rooms, as proposed to me by Dr Charles Michel, with the withdrawal of nearly all restraint, leaving the eye not operated upon open for the guidance of the patient, or the fruit of my own experiments, makes an after treatment which leaves but little to be desired

It is said that there is nothing new in all this, and such a statement is in a measure correct, as the following extract from Mackenzie on "Eye Disease," American edition, of 1855 will show

After treatment of Cataract Extraction Cases—The patient should be put to bed with as little movement of the head and body as possible The room is not to be made too dark The length of time a patient is to be kept in bed, is a point upon which there has been a wide diversity of practice Wenzel confined his patients to their backs, without change of posture, for a fortnight Phipps, on the other hand, examined the eye on the morning after the operation, applied a shade and allowed the patient to rise A middle course appears the most judicious It is improper to cover up the eye too closely, and still more improper to load it with dressings and bandages It is of the utmost importance however to keep the eyelids still, and prevent any attempts to use the eyes These objects are completely obtained by the straps of court plaster, from the employment of which I have never witnessed any bad consequences I generally allow those which are applied immediately after the operation, to remain on for two or three days, but if the eye is easy for four or five days

Desmarres in his "Treatise on Eye Diseases," published in 1847, also refers to the adhesive straps as his sole dressing From this extract so pertinent to the subject under discussion, (from Mackenzie's old work on eye disease,) it would seem that the common method of dressing eyes after cataract extractions, in Europe forty years ago, was by adhesive strips, and in moderately lighted rooms Also, while some operators were very rigid in bed restraints, keeping their patients immovable on their backs for several days, others allowed much more latitude, even to sitting up on the second day Why this good practice was abandoned and compresses with bandages substituted is not made clear Possibly the retching and vomiting accompanying the administration of a general anæsthetic, which about this time was introduced into eye surgery, seemed to demand more support and protection for the eye just cut open Now that the local action of cocaine has removed this ugly complication in cataract extractions, there is no good reason why the adhesive strap should not be reestablished and generally adopted as the best and sole dressing

The only great novelty in the treatment which I suggest is the leaving of one eye open for the guidance of the patient So far as I have consulted the old authors, I have found no mention made of this item A more careful search, however, may show that this is also no new thing

Grant it, that there is no real novelty in treating cataract cases as has been defined Operating in the amphitheatre, closing the eye operated upon with isinglass plaster, leaving the other open for the guidance of the patient, allowing him to walk from the operating room to his chamber, not putting him to bed, allowing him free movements and no restriction as to diet, or receiving the visits of friends, no disturbance of the dressings till the fifth day, then freedom from all restraints after that time, even to the exclusion of smoked glasses Also, grant that these methods as practiced by a former generation of eye surgeons have never been altogether abandoned Against all this I do not hesitate to say, that whatever may have been the method pursued in former times, it is now the habit of eye surgeons to treat cataract cases by the exclusion of light to eyes recently operated upon, by compresses and bandages, and in dark rooms and with bed restraints and afterwards by the wearing of smoked glasses Since I have found that these annoyances are uncalled for and do not add to the comfort or safety of the patient,

I have for the past year been making war systematically, against these universally established methods, because a large experience has taught me that the method of treating cataract extraction under bandage, in dark rooms and with bed restraints is unreasonable, unphysiological, and unnecessary

The year's work at the Presbyterian Eye and Ear Charity Hospital, of Baltimore, has proven to my entire satisfaction, and also to the satisfaction of many other surgeons, that the after treatment which I was carrying out is by far the most comfortable for both patient and surgeon, and is also accompanied by fewer accidents I have succeeded in making many converts to my way of treatment and before long hope to see compresses, bandages, dark rooms and restraints, considered as relics by all the friends of progress in ophthalmic work

MEDICAL PROGRESS.

THE TREATMENT OF COLDS.—DR WHITAN, R N, in a short article on the treatment of colds, says It is recognized generally that catarrhs are excited *de novo* by exposure to wet, cold, and draughts, most frequently they develop in delicate and in highly neurotic individuals When once a catarrh is properly established, the affected person's breath is infectious in the acute stage of the disease at least The question arises, What is the nature of the affection? 1 Is it a specific poison comparable to that of the infectious fevers? 2 Does the affection start as an idiopathic inflammation and develop a specific poison which is given off by the breath? 3 Is it of nervous reflex origin purely? An epidemic of influenza would be explained by supposing within large tracts of country all catarrhal micrococci become suddenly virulent, owing to some climatic or telluric fostering cause, or to some law of heredity, or evolution of the organisms themselves The usual coddling treatments of colds in an ordinarily healthy person should be strongly condemned, there is a deal of wisdom in the saying 'Starve a fever, feed a cold' A person with catarrh should take an abundance of light nutritious food and some light wine, but should avoid spirits and tobacco In the very old or very young, or in cases where the general health is not good, due care must be taken, and, above all things, depressants should be avoided The author recommends as a specific, both as a prophylactic and therapeutic remedy, the following prescription ℞ quin sulphatis, gr xviij, liquor arsenical, ♏ xij, liq atropinæ, ♏ j, extract gentian, gr xx, pulv gum acac, q s to make twelve pills One of these pills shound be taken every three, four, or six hours, according to circumstances If these pills are commenced in the early stage of a common cold, when the affection is confined to the nose and pharynx, the affection will be nipped in the bud At first one pill should be taken every three or four hours later on every six hours The author's experience goes to prove that a cold seldom lasts three days under this treatment, and believes that the remedy acts as a powerful nervine and general tonic, bracing the patient's tissues to resist the multiplication of the organisms which cause the affection —*Practitioner*, March, 1887

ACID CALCIUM PHOSPHATE INJECTIONS IN TUBERCULOUS JOINTS.—KOLISCHER recently exhibited to the Society of Physicians of Vienna four cases of tubercular joints, which he had treated by the injection into the diseased joints of a solution of acid calcium phosphate (strength and dose not reported) The method aims at the destruction of tuberculous bacilli and the induction of calcification of tuberculous matter, in imitation of what is often seen in healed pulmonary cavities It is supposed to produce a mild degree of inflammation and cicatrization, which destroys tuberculous matter In one class of cases prompt inflammatory reaction followed the injection, and this was followed by a period of calcification which lasted for from two to four weeks, and ended in absorption, the final result being restoration of the contour of the joint In another class, in which cheesy degeneration was in progress, the injections were followed in about a week by breaking down of tubercle, and rupture and discharge of the abscess, healing by granulation resulted The solution readily caused cicatrization of tuberculous ulcers and separation of necrosed bone Tuberculous fistulas and cavities were tamponed with gauze saturated with the solution Kolischer has cured two cases of acute tuberculosis of the elbow in children, with restoration of contour, normal motion, and absence of general symptoms, has greatly improved a case of tuberculosis of the knee, and has markedly benefited a case of acute tuberculosis of the carpal joint, with result of normal contour, filling of capsule with calcified material, and slight movements of fingers

PILOCARPINE IN NEURITIS AND MYOSITIS.—SEMMOLA reports the case of a lady, about 40, in good health, after standing in a draught was seized with great pain in the right shoulder and arm, the pain gradually increased, and all movement of the arm became impossible Massage, liniments, galvanism, with salicylates and quinine internally, were prescribed Months passed, but the conditions remained the same Semmola, on being called in consultation, recommended the prolonged Scotch douche, but as the administration of this was inconvenient, he suggested the hypodermic injection, every twelve hours, of a centigramme and a half (¼ gr) of hydrochlorate of pilocarpine There was considerable improvement after the second injection, and in four days the patient was practically well —*London Medical Record*, May 16, 1887

CEPHALIC VERSION IN PLACENTA PRÆVIA.—KUFFERATH thinks this operation bad practice, as we cannot hope to arrest hæmorrhage by changing a malpresentation, for the head, in cases where cephalic version is still possible, will not plug the bleeding surface —*Lancet*, June 11, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SPARTEINE AND NITROGLYCERINE IN MORPHIA HABIT

In a note on the "Modifications of the Pulse in Morphiomania," presented to the French Académie des Sciences in March, 1887, by Professor B Ball and Dr Oscar Jennings, the authors discussed the mechanism of the morphia craving, and showed that there is ischæmia of the general circulation during the period of privation, and that an injection of morhia administered at this time causes a disappearance of the psycho somatic suffering which constitutes the craving, and is followed by restoration of the pulse In a communication to the Académie de Médecine in March they stated that they had found that morphia craving can be appeased by other drugs which restore the pulse in a similar manner "We thought," they say, "it would be preferable to try heart tonics, and strengthen the action of this organ in moments of weakness To this end we have employed sulphate of sparteine, which fulfils most of the conditions, and can easily be administered by hypodermic injections We watch for the moment of weakness as indicated both by plateau in the sphygmographic tracings and by the intimate sensations of the patient At this moment we administer an injection of from two to four centigrammes, which may be repeated when necessary, and at the expiration of a few minutes we see the pulse strengthen and the craving disappear Another medicine which procures a passing relief of the symptoms is nitroglycerine Its effects, very similar to those of sparteine as regards the point in question, are at the same time much more rapid and much more ephemeral"

Since these reports were made DR JENNINGS reports, in the *Lancet*, of June 25, that he has administered sparteine and nitroglycerine repeatedly in fourteen different cases, and he is convinced that in these agents, properly administered, we possess a means which will enable any morphia habitué earnestly desirous of leaving off his intemperance to give up the habit That treatment of this kind is better than restraint need scarcely be argued Sparteine and nitroglycerine should be used only when really needed, and should not be at the patient's disposal Dr Jennings' experience is that the effect of nitroglycerine is most satisfactory and persistent in those cases in which there is a predominance of the "yearning" over the "craving"—in which the psychical symptoms are more distressing than the bodily But when there is more physical craving than mental suffering (morphia nostalgia) sparteine, which is a tonic to the circulation, gives better results than nitroglycerine alone And in the simultaneous administration of the two drugs, the one by hypodermatic injection, the other placed upon the tongue, Dr Jennings thinks we have a perfect remedy for the morphia craving in its double psycho somatic modality He thinks it will be found that those patients who say they receive no benefit from this treatment do not desire to be cured

DIGESTION OF LIVING TISSUE AND SELF DIGESTION

It is well known that partial digestion of the stomach takes place after death, and similar changes have been observed in the lower animals Frenzel would explain the rapid dissolution of amœbæ and infusoria on the theory that they are dissolved by a digest formed within themselves during life But the question has often been asked, why does not the living human stomach digest itself? The usual answer is that the alkaline blood circulating in the walls of the stomach prevents the action of the acid stomach juices Claude Bernard and Pavy found that the limb of a living frog or ear of a rabbit introduced into the stomach through a fistulous opening will be partly digested In order to test the matter further FRENZEL, (*Centralblatt fur Physiologie, No 1, Biologisches Centralblatt, vi, No 22*) has immersed a frog's leg in a solution of pepsin and a 2 1000 solution of hydrochloric acid In a short time the skin loosened in pieces, the muscles dissolved, and within an hour and a half the bones were bare The blood vessels were attacked as readily as other tissues After this experiment the solution in which the limb had been

immersed gave the usual reaction for pepsin The second leg remained unaffected in a two per cent solution of hydrochloric acid Under the influence of the pepsin acid solution the skin was first killed and then digested In a neutral pepsin solution a tadpole lived for twenty-four hours In these cases the alkalinity of the blood did not protect the living tissues The protection of the intestinal wall is usually ascribed to the mucus, but why cannot the pancreatic juice diffuse itself through the mucous layer This mucus is entirely wanting in the intestines of insects Why self digestion does not take place is as yet unexplained

CONDITIONS OF MEMBERSHIP IN THE NINTH INTERNATIONAL MEDICAL CONGRESS

"Rule I The Congress will consist of such members of the regular medical profession as shall have registered and taken out their ticket of admission, and of such other scientific men as the Executive Committee of the Congress shall deem desirable to admit The dues of membership for residents of the United States will be ten dollars ($10) There will be no dues for members residing in other countries Each member will be entitled to receive a copy of the *Transactions* of the Congress when published by the Executive Committee "

This rule, plainly defining the conditions for acquiring membership and participation in the approaching International Medical Congress, was adopted and published in English, French and German, in Circular No 1, issued and widely distributed in both this country and Europe by the Executive Committee more than two years ago It was repeated in Circular No 2, issued in July, 1886, and also republished in most of the medical periodicals of this country And yet we notice that some of our State and local medical societies have appointed *delegates* to the Congress, and we are often receiving letters making inquiries touching the same subject Hence we have again quoted the rule, and wish to state explicitly that the doors of the Ninth International Medical Congress will be open to all members of the regular medical profession, in all countries where such profession exists, who may apply to the Registration Committee in Washington, D C, enter their names in full on the roll, and take their tickets of admission Those residing in this country must pay at the time of registering the $10 From those residing in other countries no fee will be required

In regard to the registration of educated dentists, about which there has been some question, it is sufficient to say that the same rule will be followed as governed at the London Congress of 1881 The establishment of a Section of Oral and Dental Surgery is a full admission that it constitutes a part of the domain of general medicine and surgery, and that all who, by education and proper legal authority, practice in that special department, are "members of the regular medical profession " At the London Congress they registered with the common prefix "Dr," as did a large proportion of eminent members of the profession in other departments At the Congress in Washington it will be proper for them to register with the title Dr, M D, D M D, or D D S, according to the terms of the authority conferring upon them the right to practice their profession

FOURTH OF JULY CASUALTIES

As has been pertinently remarked, it is probable more people have been killed and maimed on July 4 since the establishment of this country's independence than were hurt by the British forces which attempted to shut off the present noisy celebrations And were Cornwallis and Burgoyne living to-day they might consider themselves amply revenged It cannot be doubted that the country would be better off if fire works and instruments of pyrotechnic patriotism could share the fate of the tea in Boston Harbor

The "celebration" casualties thus far reported in this city amount to almost fifty, some fatal and many serious The greater number are pistol shot wounds and injuries to eyes from explosions Besides these there were almost thirty fires caused by carelessness with explosives It seems that the American public might find some less dangerous method of manifesting its exuberant patriotic feelings, and surely it is within the province of health officers to bring the dangers more prominently to the notice of the public authorities There are ways in which fire-works may be safely indulged in, but the present freedom in the matter given to small children is unsafe Nor does the matter end with those who are in good health (at beginning of the day), the noise, which is sufficiently distracting to healthy adults, is undoubtedly a source of positive danger to very many sick persons It is much to be regretted that *the* events of July 4, 1776, did not take place on February 29 of that year

NEW TEST FOR MILK —SZILASI, according to the *Lancet*, of June 11, has recently proposed a new test

for pump water in milk It is based on the fact that sulphate of diphenylamine is colored blue by the action of an exceedingly dilute solution of a nitrate As well water always contains more or less nitrates, its presence in milk can be detected The test is thus carried out Twenty minims of sulphate of diphenylamine is placed in a small porcelain vessel, and a few drops of the milk to be examined are added to it If the milk contain even 5 per cent of average well water a blue tinge will gradually distinctly appear Sulphate of diphenylamine is very cheap, so the test may be readily tried

MORE LIBERAL CONTRIBUTIONS —We are informed that at the recent regular meeting of the New Jersey State Medical Society $400 were contributed to the entertainment fund of the International Medical Congress, and at the annual meeting of the Pennsylvania State Medical Society $1,000 were appropriated from the treasury, and $200 more added by individual contributions, thereby making the total $1,200 Thus the good and *necessary* work goes on

WESTERN PENNSYLVANIA MEDICAL COLLEGE — From the Announcement of the new Medical College at Pittsburgh, Pa, we learn that the class of students attending the first regular annual term numbered 57, of whom 21 received the degree of M D, which constitutes a very gratifying beginning The next regular college term will commence on the last Tuesday in September, 1887, and end on the 24th of March, 1888

SOCIETY PROCEEDINGS

ASSOCIATION OF AMERICAN PHYSICIANS

Second Annual Meeting, held in the Army Medical Museum Building, Washington, June 2 and 3, 1887

(*Concluded from page 24*)

THURSDAY JUNE 2, FIRST DAY

EVENING SESSION

The discussion on

HÆMORRHAGIC INFARCTION,

was opened by DR W M WELCH, of Baltimore, Referee Numerous experiments had been performed by Dr Welch with the assistance of Dr Mall, of Johns Hopkins University, to determine which of these theories was the correct one He presented as the result of his studies the following conclusions

1 The blood which produces hæmorrhagic infarctions comes chiefly, if not exclusively, from the collateral vessels

2 Hæmorrhagic infarctions in the intestine cannot take place merely from a reflux of blood from the veins

3 The blood pressure is very low in the region where hæmorrhagic infarction occurs in consequence of occlusion of the main artery

4 A certain degree of force of the collateral circulation is required to produce a hæmorrhagic infarction

5 No positive proof exists that a change in the vascular walls is essential to the production of a hæmorrhagic infarction

6 The hæmorrhage occurs by diapedesis

7 When hæmorrhagic infarction has taken place, the large and small veins are widely dilated with blood, and the arteries contain a smaller quantity of blood than normal There is stasis *in many of the veins and capillaries*

DR WILLIAM OSLER, of Philadelphia, the Coreferee, referred to the clinical aspects of the subject He reported the following case, J M, age 20, admitted to the Philadelphia Hospital, October 10, 1886 He had never had syphilis and was a healthy looking man He presented a clear history of typhoid fever with a sickness of six weeks, two years previously His present illness began with diarrhœa one week before admission For two days he had attacks of bleeding at the nose There was temperature of 102° with pain in the abdomen There was no cardiac murmur and examination of the lungs gave negative results The splenic dulness was increased By October 15 the temperature had reached 103° There was almost constant delirium There was some diarrhœa. Coldness of the feet appeared, and continued to increase in degree and extended up the leg The legs became tired and no pulsation could be detected in the femoral and popliteal vessels The patient died on the 17th It was supposed that there was thrombosis of the iliac veins with gangrene of the legs, which is one of the rare sequences of typhoid fever At the autopsy it was found that the lower portion of the abdominal aorta and also the two iliac arteries were plugged with thrombi There was general peritonitis, the right kidney presented a red brown infarction There were no ulcerations in the bowel, no endocarditis The lungs were normal There was an infarction in the spleen During life the blood was examined for microbes but none were found After death microbes were found in the spleen

Hœmorrhagic infarctions of the liver under ordinary circumstances is impossible A B, a hard drinker was admitted to the hospital September 27 His illness began in the previous June with vomiting and swelling of the abdomen The dropsy steadily increased He died two days after admission At the autopsy a large amount of fluid was found in the peritoneal cavity There was nothing special found in the heart or lungs The liver was remarkably cirrhotic Through the right half of the right lobe there were scattered numerous reddish-brown areas The walls of the portal vein were thickened and a large brown thrombus occupied the upper portion of its trunk The branches passing to

the right lobe were filled with clots The hepatic artery and vein were normal In this case the hæmorrhagic infarctions were in all probability due to the cirrhosis of the liver which had caused more or less obstruction of the branches of the hepatic artery The only other case of infarction of the liver which the speaker had been able to find was one reported by Recklinhausen

In the intestine hæmorrhagic infarctions are met with in two forms, one involving the mucosa, the other affecting the entire gut The former not infrequently ends in ulcerative necrosis The latter form of hæmorrhagic infarction is not common in man In the horse it is frequently seen resulting from thrombi formed from verminous aneurisms of the mesenteric and its branches This is a common cause of the severe and fatal colic so frequently seen in these animals In conclusion the speaker referred to the fact that in the lung it was not uncommon to have a vessel blocked without the production of an infarction An occasional cause of thrombotic infarction is local diseases of the pulmonary artery It sometimes results from the endarteritis induced by beginning tubercular processes

FRIDAY, JUNE 3, SECOND DAY

DR E T BRUEN, of Philadelphia, read a paper on

BERGEON'S METHOD OF TREATING PHTHISIS

With reference to the effect of the injections of sulphuretted hydrogen on the bacillus tuberculosis, Bergeon does not claim that their number has been reduced in any considerable proportion of cases If the bacillus be the real cause of the disease we lack any agent which will destroy it Since February last he had employed Bergeon's method of treatment in sixty one cases Forty four of these cases have been benefited, but of these only three appeared to regain full health Two of these were cases of incipient phthisis with apparent consolida- of the apex of the right lung In one of these cases the bacillus tuberculosis was not found although five examinations were made In the other case the bacillus was found In these cases the apparent recovery has been associated with a decided increase in weight He believed, however, that the disease is simply latent The third case was one of broncho pneumonia In all the other cases the lesions were more or less advanced with the presence of cavities and profuse expectoration In the fifteen cases in which a negative result was obtained, the treatment in some was followed by temporary benefit The good results have consisted in lessening of the expectoration, diminution of the cough, lowering of the temperature and suspending of the night sweats In most of the cases there was a diminution of from fifteen to twenty beats in the pulse, and a diminution of half a degree in the temperature during the administration of the gas Even in those cases which were benefited, and in which the temperature had been brought to normal, there would be during the progress of the treatment occasional outbreaks with a return of the fever and the other symptoms These, however, disappeared under a continuance of the injections In order to determine the effect of the treatment on the bacilli, Dr E O Shakespeare made a number of examinations during the progress of the cases There has been no diminution in the number of the bacilli It was, however, thought that in those cases where the treatment had been continued for some time the reaction of the bacilli to the staining fluid was less marked Two cases have died, in one of these an autopsy was made This case had been under treatment for two months The walls of the cavity were moderately smooth and firm, but there was no tendency to cicatrization The results were of a decidedly negative character

Bergeon's method is chiefly valuable in those cases attended with bronchial catarrh He had had very little good effect in those cases where there was thickening of the lung without much catarrh The speaker feared that the trouble and detail necessary to the successful application of this method and the limitations of its power would cause it to be set aside for other therapeutic measures

DR F C SHATTUCK, of Boston, read some

CLINICAL NOTES ON BERGEON'S METHOD OF TREATING PHTHISIS

He had treated only seven cases by this method He had seen such improvement follow careful dietetic and hygienic management that he had not much confidence in the results claimed for special methods of treatment in these cases Any new method of treatment will often have an apparently beneficial effect through its influence on the mind, even in those cases which are incurable Six of the cases treated suffered with phthisis and five were in an advanced stage of the disease One was a case of chronic bronchitis with asthma and emphysema Four of the patients suffered with more or less pronounced collapse from the use of the injections Nausea, vomiting and diarrhœa occurred in several cases In one case, although the patient was weak, no local or general ill effect was observed In another case the treatment was continued four weeks with no ill effect The only benefit obtained was a diminution of the expectoration He presented the following conclusions

1 Toxic symptoms may follow the injections of sulphuretted hydrogen gas These are nausea, vomiting, general depression, collapse and perhaps headache

2 Strong artificial solutions of sulphuretted hydrogen gas with carbonic acid gas are apt to cause abdominal discomfort The risk of this is diminished by heating the solution of the former gas

3 This is not by any means a specific If useful at all it is only as an auxiliary to the more useful methods of treatment

4 The only benefit which we have seen that could be fairly attributed to the enemata was a diminution in the amount of the expectoration

In conclusion, the author stated that the impression which he had formed was that the good results which had unquestionably followed this method

of treatment, were attributable in large part to the stimulation induced by the employment of a novel method of treatment, which makes the patient feel that something is being done for him

Dr William Pepper, of Philadelphia, employed this method in twenty four cases Other treatment was frequently combined with the use of the injections In no case was the temperature brought from a febrile to a continuously normal condition The fall was not more than is seen in similar cases under other methods of treatment In twenty cases where the weight was recorded, there was in eight more or less gain Light pounds in 37 days was the greatest gain In six cases the weight remained stationary, and in six it was diminished The improvement in cough was not marked The expectoration was somewhat diminished in four, out of twenty four, cases Search was made for the bacilli in thirty cases and they were found in twenty seven In eleven cases the examination was repeated and only in four was there any apparent decrease Cases of night sweats were not numerous In one they were checked and in seven improved Physical examination showed no improvement in a single case The enemeta had a decided hypnotic influence in three cases The only unpleasant symptom of any real moment was colic This was complained of in eleven, out of twenty four cases Three others suffered so much that the treatment could not be repeated The colic was not often controlled by giving smaller quantities of the gas, nor did it seem to be influenced by the slowness of the injection

Dr H C Wood, of Philadelphia, after studying the cases treated by this method, came to the conclusion that it was of a certain amount of benefit The sulphuretted hydrogen should accomplish the same results when absorbed by the stomach as when taken up by the large intestine He had therefore administered the sulphuretted hydrogen gas in carbonic acid water He thinks that this is a distinct addition to pulmonary therapeutics He had tried it in certain cases with benefit

Dr Beverly Robinson of New York The pain which is experienced in many cases may be due to the fact that there are ulcerations in the intestine These may be present without the existence of diarrhœa I have under treatment a case in which the tubercular deposits in the lungs is associated with ulceration of the larynx The man has received a daily injection for the past ten days There has not been the slightest change in the appearance of the larynx

Dr James T Whittaker, of Cincinnati, had used the sulphuretted hydrogen gas both by injection and also by inhalation The effects under both methods of administration seem to be the same It mitigates the cough, relieves the fever, and lessens the night sweats It is, however, not a specific

Dr F P Kinnicutt, of New York, read a paper on

ATROPHY OF THE GASTRIC TUBULES—ITS RELATION TO PERNICIOUS ANÆMIA

He gave the histories of two cases in which the typical symptoms of pernicious anæmia were well marked At the autopsy in each of these cases nothing special was found in any organ but the stomach The inner surface of the organ was smooth Microscopical examination was made of numerous sections removed from different parts of the stomach Throughout a large extent no trace of gastric tubules was found In some parts the more superficial portions of the tubules could be found but the deeper portions could nowhere be made out There was also seen a peculiar hyaline substance in the shape of tubes and of drops Numerous irregular cells were seen near the surface of the mucosa The author thought that in this lesion of the stomach was to be found the explanation of a certain number of cases of pernicious anæmia

---

AFTERNOON SESSION

Discussion of Dr Kinnicutt's paper

Dr Francis Delafield, of New York, said that in a number of cases marked changes in the mucous membrane of the stomach have been found He looked upon the lesion of the stomach as secondary and not primary

Dr F P Henry, of Philadelphia, The cases reported by the author taken in connection with other cases which have been recorded, demonstrate that there is a form of anæmia associated with, and I think dependent upon, atrophy of the gastric tubules That this condition is primary, and not secondary, is I think sufficiently attested by the fact that it is not found in any other condition

Dr William Osler There is unquestionably a group of cases of pernicious anæmia in which there are serious lesions of the gastric mucous membrane, although these lesions are not always the same I think that it is quite impossible to distinguish clinically the cases with gastric atrophy from the cases without these lesions In a case of two years' standing although the symptoms were marked, the autopsy revealed no serious lesion of the stomach

Dr E C Seguin, of New York, read a third contribution to the study of

LOCALIZED CEREBRAL LESIONS

The third case reported related to the location of the facial centre The patient, a boy of 7 years, was first seen in January, 1885 He had been complaining of numbness in the right hand The right leg and arm were slightly paretic There was no headache, and no aphasia Shortly after this, clonic convulsive movements occurred in the right cheek and both eye balls were turned to the right This lasted for over two hours At times the speech was thick There was no history of previous injury, and there was no evidence of pulmonary, renal, or arterial disease There was no cranial tenderness on pressure The tongue when protruded deviated to the right The diagnosis was meningeal adhesion over the precentral region Iodide of potassium was given in gradually increasing doses until from sixty to seventy-five grains were taken Early in April of the following year, symptoms of tubercular meningitis devel-

oped and the child died, after an illness of three weeks At the autopsy, the ordinary lesions of tubercular meningitis were found In addition there was a patch of adhesion situated over the left pre central gyrus and the caudal part of the second frontal gyrus This was one inch in diameter This would indicate that in the human brain the facial centre is in the caudal end of the second frontal convolution

The second case related to the situation of the leg centre A patient aged 49 years, suffered with paresis of the right leg and clonic spasm of the right abdominal muscles There were right hemi-epileptic attacks, the spasm beginning in the abdominal muscles and extending to the arm and leg These attacks were repeated without loss of consciousness Paralysis of the right leg and paresis of the right arm developed *There was no aphasia and no choked* disc Attacks of a syncopal character occurred, in one of which the patient died At the autopsy a large sarcomatous tumor was found, involving the cortex of the paracentral region gyrus Two small nodules were found in the white substance below the principal tumor This would indicate that the nerve centre for the leg was in the paracentral lobule

DR JAMES J PUTNAM, of Boston A man of 45, suffering with locomotor ataxia probably of syphilitic origin, suddenly developed convulsions of the right arm and leg, without loss of consciousness, and without change in the voice The symptoms relating to the arm entirely passed away, but the leg never recovered its normal condition The patient died some time later, and at the autopsy a small hæmorrhage was found at the lower edge of the paracentral lobule

DR F T MILES, of Baltimore A patient with Bright's disease suddenly became hemiplegic without the voice being affected The arm and leg were affected He rapidly improved, but the leg remained weak He complained a great deal of a dragging in the shoulder At the autopsy the only lesion that could be found was a hæmorrhage of the size of a bean in the paracentral lobule

DR H H LYMAN, of Chicago Some months ago I saw a case in which there was a sudden convulsion without loss of consciousness, the left arm being principally affected These convulsions were repeated There was a paretic condition of the left arm, which in a few days extended so as to involve the corresponding leg The convulsive movements of the upper extremity continued to recur They did not involve the face The patient died and a sarcoma was found on the right side occupying the position of the centres for the arm and leg

DR JAMES J PUTNAM, of Boston, read a paper on

FREQUENCY WITH WHICH LEAD IS FOUND IN THE URINE, AND THE SYMPTOMATOLOGY OF CHRONIC LEAD POISONING

This paper consists of analyses of eighty-six cases in which the urine had been examined for lead The following conclusions were presented

1 It is probable that lead may cause neurasthenic symptoms which may exist for a long time without other signs of poisoning

2 The same is true of fine muscular tremor, especially if associated with debility

3 The most important conclusion is, lead seems to cause, occasionally, a greater or less degree of the symptoms classed as spastic paraplegia, instead of the usual type of paralysis with atrophy and loss of the deep reflexes

4 Additional evidence is furnished of the importance of suspecting lead as a cause of vague cerebral symptoms such as are often due to syphilis

5 In one case of epilepsy in a person not predisposed, and where the probable first attack occurred at the age of 25, besides the discovery of lead in the urine, there was a slight weakness and impairment of electrical reaction of the long extensors of the fingers

Two cases of ataxia with extensor muscular atrophy, and other signs of peripheral neuritis, were reported, probably due to lead

DR I E ATKINSON, of Baltimore, read a paper on

FORMS OF TYPHOID FEVER SIMULATING REMITTENT MALARIAL FEVER

The object of the paper was to describe forms of typhoid fever in which all the usually characteristic symptoms are absent except mild fever These cases commonly occur during the late summer and early autumn They begin with a chill or insidiously, and assume a course of mild remittent type, never passing into a typhoid condition, never developing the characteristic symptoms of typhoid, yet absolutely uninfluenced by antiperiodic treatment They last three, four, or even five weeks, and almost always end in slow lysis and recovery They resemble malarial conditions except in the persistence of fever under strongly anti malarial treatment, and in the occasional concurrence of circumstances pointing to a typhoid origin There is no hebetude, the patient sleeps well, the tongue is slightly coated, there is almost never epistaxis, constipation is commonly observed, there are no bloody stools, no tympanites, no iliac tenderness or gurgling, and rose spots are usually absent The patient is bright and cheerful The more severe cases, after beginning as remittents, may gradually evolve typhoid symptoms Three cases were reported showing the type of fever described, occurring under conditions indicating their typhoid origin The diagnosis of these cases from remittent malarial fever often rests upon the crucial test of treatment It is admitted that occasionally antiperiodic remedies fail to control the malarial paroxysm, especially in pernicious and adynamic forms In milder forms the behavior under quinine practically solves the difficulty Where the full administration of the antiperiodic remedy for a number of days fails to terminate the attack, the diagnosis of typhoid fever becomes justifiable, and the prognosis can be made with a high degree of confidence Not often earlier than the second or later than the fourth week the fever will terminate, almost constantly by lysis, rarely by crisis In the future, a solution of the difficulty of diagnosis will be obtained through the knowledge derived from bacteriological research and culture observations

DR WILLIAM H DRAPER, of New York Dr

Atkinson has spoken of the aid given by quinine in the diagnosis My own experience confirms that of others with reference to the use of quinine as an antipyretic in typhoid fever Unless used in such doses as to produce a certain degree of collapse, it is useless, I believe that it does nothing more than to increase the discomfort of the patient If, in five or six days, the use of quinine does not succeed in checking the fever, we may conclude that we are dealing with a continued fever of the nature of typhoid

Dr John Guitras, of Charleston I have had an opportunity of studying these cases both in the North and in the South, and I have come to a conclusion different from that expressed by the author These cases present no symptom of typhoid fever with the exception of the continued fever, and this is a strong argument against their being typhoid These cases are so numerous as we go farther South that I would class them as a separate disease I have examined some of these cases of prolonged continued fever of southern countries *post mortem*, and have failed to find the lesions of typhoid fever In the South we have these three diseases, malarial remittent fever at one end, typhoid fever at the other, and between these we have cases of the kind described by Dr Atkinson My view of this fever is that it belongs to the class of functional fevers A simple continued fever may be set up by an excessive demand made upon any of the important functions of the body I have thought that in warm climates where constant exertion was required on the part of the heat centres to keep within limits the production of heat, a paralytic condition of these centres might be induced especially towards the close of a long and hot summer This fever presents none of the symptoms of a malarial affection, and is quite common in sections where malaria is unknown

Dr A Jacobi, of New York I think it a mistake to say that those cases in which the fever cannot be broken in five or six days by quinine are not malarial There are cases of remittent fever that will not be broken by quinine There is one aid in diagnosis which I have not heard alluded to, and that is the urine test This has frequently been of much service to me It is prepared as follows

Solution No 1 Sodium nitrite 1 part, water 200 parts
Solution No 2 Sulfanilic acid 5 parts, concentrated muriatic acid five parts water 100 parts
Add 1 1–5 part of the first solution to 50 parts of the second

Equal parts of this mixture and the urine are to be mixed Then add about 60 or 70 per cent of aqua ammonia In normal urine there will be only a slight discoloration, while in urine from typhoid fever there will be a deep purple discoloration

Dr R. H Fitz, of Boston An epidemic of an anomalous form of fever recently occurred in Boston among a number of emigrants The diagnosis lay between typhoid and typhus fever It was concluded that they were cases of typhoid fever One case ended fatally The intestinal lesions were of the most trivial character The enlargement of Peyer's patches was no greater than is seen in many cases of enteritis The lesions were so superficial that it seemed quite probable that they would have disappeared if the case had lived a few days longer

Dr W T Councilman, of Baltimore I think that a simple examination of the blood will enable us to differentiate between the continued malarial fevers and typhoid fever The organisms found in these cases of continued malarial fevers are very easy to recognize

Dr William Osler I have had three cases in which the examination of the blood aided in the diagnosis One was a case of continued malarial fever thought to be typhoid, another was a case of remittent fever supposed to be typhoid In both these instances examination of the blood showed the case to be malarial In the third instance the patient had a chill, which was repeated It was supposed to be a case of remittent fever, but the malarial organisms were not found The case pursued an atypical course, and when two weeks advanced in convalescence had a well marked relapse of typhoid fever

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted, and Dr William Pepper, of Philadelphia (with Dr Reginald H Fite, of Boston, as alternate), was appointed as the representative of this Association

OFFICERS FOR THE ENSUING YEAR

President, Dr William H Draper, of New York
Vice Presidents, Dr Francis Minot, of Boston, and Dr J Palmer Howard, of Montreal
Recorder, Dr William Osler, of Philadelphia
Secretary, Dr Henry Hun, of Albany
Treasurer, Dr W W Johnston, of Washington

The following were elected to active membership Drs A V Meigs, Louis Starr and J H Musser, of Philadelphia, Dr James E Reeves, of Wheeling, W Va , Dr William H Whitney, of Boston, Dr James Stewart, of Montreal, and Dr N Allen Starr, of New York

Dr John S Billings, of Washington, was elected to honorary membership

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, March 30, 1887

The Vice President, D S Lamb, M D, in the Chair

Dr S Lamb presented a specimen and gave the history of

A CASE OF SHOT WOUND OF LUMBAR SPINE, THE BALL LODGING IN THE CANAL, AND REMOVED AFTER DEATH, 18 5 YEARS AFTERWARDS

The situation of the injury of this case and the length of time which elapsed between the wounding and death seem to me sufficiently important to make it worthy of as minute a record as possible The historical data were mainly obtained from the mother of the patient, through letters written by him, and from his widow

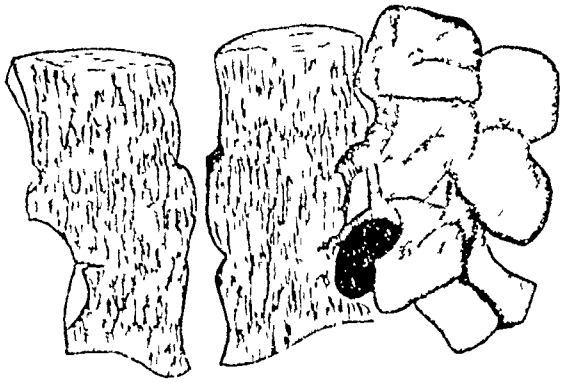
John H S then Corporal Comp "C," 36th Mass, of temperate habits Wounded May 8, 1864, at Spottsylvania court house, Va A rifle bullet entered the lumbar region, and lodged in the lumbar spine He lost at once the use of his lower limbs, was admitted to Field Hospital, wound probed for several inches without finding missile For four days the urine had to be drawn by catheter, and for a long time the fæces were removed by a rectal spoon May 13, was transferred to Campbell Hospital, Washington, arriving next day, stood the journey fairly well, 17, laudable pus discharging freely, sleeping fairly at night, 19, able for the first time to wash himself, 25, sitting up in bed propped by pillows, 28, could use all his limbs except his left foot, wound quite painful He gained strength slowly, by June 16, wound was nearly healed, and not very painful, but *there was pain in hip*, 23, back had been very painful at times, the pain beginning as a cramp and doubling him up, this recurring ever time he moved July 3, for the first time could lie on his back, had lain on his face and sides, still the cramping pain, 9, the cramps less troublesome, 16, leg aching badly, explained by gradual return of circulation of blood, 18, unable yet to use left foot, no sensation in left leg, 26, could move his legs about and bear some weight on right August 4, wound discharging again with less pain, in *trying to move left foot it doubled up, the toes* and heel nearly touching, 8, able by himself to get into a sitting position on edge of bed Cold compresses and ice had been pretty regularly applied to the back, 22, only able to sit up a little while at a time, because the weight of the upper part of the body seemed too great for the wounded back and caused intolerable pain, could stand up but left foot was useless September 1, sitting up, dressed, 17, furloughed to his home, arriving the 19th, tired out, although accompanied all the way by a hospital steward Was now confined to his room for nearly four weeks, could then move about without help, bowels generally regular, but there was dysuria, had much pain in back, no sensation in left foot December 3, returned to hospital from furlough, arriving the 5th and feeling very well, 24, discharged from service because of disability Returned home, applied himself to study at commercial school About February, slipped and hurt his back, causing severe pain for several days He grew steadily stronger July 17, 1865, appointed clerk in Treasury Department, Washington, his back was now much less painful and he had the use of all his limbs except the left foot The next information is that in 1868–9, at the Massachusetts General Hospital, Boston, a fragment of shell was extracted from the right thigh Dr W W Potter saw him in 1869 and found the temperature of the left lower limb, below normal, motion and sensation impaired and no muscular control over ankle joint This year he married He was then rather thin in flesh, had occasional severe pain in back, urine retained sometimes for twenty four hours and always passed with straining, constipated habit, under side of left leg and thigh cold, toes of left foot bent under, and so continued the rest of his life, he could throw the leg out but could not bend it, it felt most comfortable when elevated, during sleep there was spasmodic twitching of this leg Dr J O Stanton saw him in January, 1873, found partial paralysis of left leg, both motion and sensation, *with poor circulation, and foot* and ankle swollen, also open ulcer just above left hip joint discharging freely In May, 1874, Dr Cornelius Boyle being in attendance, Dr N S Lincoln in consultation opened an abscess of left hip and removed pieces of flannel, probed the wound to a depth of seven inches Patient unable to leave his bed till April, 1875 After this he had constant pain in back and left leg, especially in little toe, with slight intermissions of relief till death, when the toe was painful there was also vomiting He is said to have *had chills, fever and sweating every night, and the* mouth was drawn to the right side Dr Stanton saw him from time to time September 4, 1877, found the wound of hip healed up In August, 1881, the skin around left ankle broke, and discharged serum for the rest of his life, the veins of the limb being large In 1881–2 his right leg became thinner, the veins around the ankle large, but foot not swollen, left leg measured twenty two inches around calf In December, 1881, after complaining some time of headache, he had a tetanic spasm and was unconscious, similar paroxysms recurred in June, August, and on October 17, 1882, and he died the 18th *During the last two years of life* he was unable to attend to his clerical duties

Necroscopy by Dr Lamb, by request of Dr Stanton Body well nourished There was a depressed scar in right groin nearly one inch long, a second scar over lateral aspect of left ilium just below crest, a third one, circular, shallow, depressed and radiated, ¾ inch in diameter, one inch to left of middle line of back and just above level of crest of ilium

Right temporal muscle darkly congested, but there was no external sign of injury, *dura mater strongly* adherent to calvarium anteriorly, pia mater much congested, brain firm, puncta vasculosa well marked

Spine, last four lumbar vertebræ, cancellous substance red, the bodies showed abundant new formations of bone on anterior surface, and mainly on right side, most marked on fourth lumbar and adjoining cartilaginous plates, and third and fifth bodies, where there was a long thick exostosis, slight exostotic growth on the bodies posteriorly The body of the fourth showed posteriorly a conical depression, apex forwards and towards the right, one inch deep, and communicating by fistulous canal with tissues on front of cartilage between fourth and fifth vertebræ Posterior portion of body of fifth vertebræ also excavated to several lines in depth, encroaching rather on left side The section of the bodies showed the second was normal, for the remainder there was a dome shaped wedge of bone, apex of dome forwards, involving anterior part of fourth body, the wedge including the adjacent cartilages which were completely ossified and

adjoining parts of third and fifth vertebræ, this



wedge was denser than the rest of the bone and contained patches of compact substance There was some shortening of the total height of these anchylosed bodies, these three including the ossified cartilages measured but three and one eighth inches, while the normal second body was one and one eighth inch high There were flattened exostoses on the posterior wall of the spinal canal of the third to fifth vertebræ, their articular processes anchylosed, exostosis on right fourth transverse process anteriorly and fifth posteriorly, spinous processes of same three vertebræ united by bone, inter laminar spaces nearly closed by new bone To left of notch, between third and fourth laminæ posteriorly, were vertical lead marks, and in anterior part of body of fifth vertebræ, near lower edge, a little to left of middle line, a small fragment of lead was imbedded

Spinal cord Cauda equina opposite second vertebra normal, thence to the sacrum the nerves were so adherent and surrounded and infiltrated by inflammation as to be, *as such*, unrecognizable, and in this mass were small bits of bullet and larger pieces of bone, there was also some induration in the sacral portion of the cauda, and some fat in the canal The bullet lay in the depression in the posterior part of the body and adjoining left lamina of fifth vertebra, it lay with its apex forwards and showed loss of substance on one side of apex and same side of base, apex flattened, weight, one ounce and one grain, marks of saw in one side

Lungs much congested, heart appeared normal, liver and pancreas normal, spleen small, stomach and intestines normal, kidneys large, left weighing 6 5 oz , both very firm, capsule normal, cortex pale

The soft parts around the last three lumbar vertebræ showed dense inflammatory thickening several lines thick, from this place to each groin and to crest of left ilium was like thickening

The salient points of the case are these As shown by the scar, the bullet entered just to left of middle line and above crest of ileum, left side, and took a direction from left to right, upwards and forwards As shown by lead marks it passed between third and fourth laminæ, left side, into the canal and imbedded itself in the body of the fourth lumbar vertebra, rather in its right side The injury to the cauda equina is shown by the foreign bodies and consequent inflammation, hence the persistent low temperature of left lower limb, paralysis of motion and sensation of left foot, spasmodic contractions, habitual constipation and retention of urine I think that the first paraplegic condition was partly due to the injury to bone, and was therefore more in the nature of shock The primary injury of the bone was followed, of course, by inflammation, suppuration around the bullet gradually loosened that missile and caused it to drop lower in the canal behind the body of the fifth vertebra Portions of the bodies of the third and fifth, with most of the fourth, and the intervening cartilages, became one common piece of bone, whose total height was much under the normal, a fistulous tract also formed, leading forwards, abundant periostotic growths appeared on all the surfaces of these three vertebræ, both bodies and laminæ The inflammatory induration of tissue leading to each groin was doubtless due to pus following the coarse of the psoas fascia, the scar in the right groin was perhaps the point of exit on that side, but there is no history bearing on this There is no appearance of exit of pus in left groin, *nor any history* The scar on left hip is explained by the purulent sinus opened by Dr Lincoln to remove the bits of flannel, in May, 1874 No history could be had of the shell wound, beyond the removal of the fragment, no scar was noticed There is another thing not explained, viz , the fragment of lead imbedded in the anterior surface of the fifth vertebræ, it is impossible to conceive that a fragment of the bullet already described could have been in any way deflected to this location, and hardly possible to think of such a piece being driven through from the back

The diagnosis of this case was gunshot *flesh* wound of back I have not found a case near enough like it in injury, reported in the surgical volumes of the history of the late war, and with which I might compare it Recoveries from shot fractures of bodies of vertebræ are rare at the best, and it is not often that opportunity is afforded to examine the recovered cases, and determine beyond a doubt the location and extent of injury

DR N S LINCOLN reported a case of

POISONING BY BROMIDIA

He said that he had been requested to report the case, not on account of any scientific interest attached to it, but to show the danger of some of the proprietary medicines that people are in the habit of taking The victim in this case was a lady who had been for several years addicted to stimulants, and had also used chloral and chloroform Once, while in Boston, she took an overdose of chloral and came very near killing herself She was, however, resuscitated, and after that she gave up the use of drugs and alcoholics for about a year A short time ago, having by request visited the lady, he found her with a sore throat, and had also reported that she had not been sleeping well lately For her sleeplessness she requested to be given morphine hypodermatically This Dr Lincoln refused to do, but gave her instead a gargle for her throat He went to see her again on the evening of the same day, and on his arrival at

the house he was informed by the husband that his wife was up-stairs quietly sleeping Dr Lincoln went up to see her, and found her in a comatose condition and sinking rapidly Upon inquiry he heard from her daughter that the patient had been given a dose of the medicine prescribed by him, and that she had also taken some stuff from another bottle This bottle was hunted up and found to have contained bromidia With this for a clue to her condition he injected strychnia, applied warmth and electricity, and kept up artificial respiration He had it in mind to inject caffeine and atropia, but the supply of caffeine obtained was not good, and he dreaded to give together atropia and strychnia The lady died

It was found that the bottle, which contained 2 ounces of bromidia, had been purchased that day, and that during the preceding twenty days she had had the bottle filled four times As bromidia is said by the manufacturers to contain 15 grains each of chloral hydrate and bromide of potassium, with 1/8 gr each of canabis indica and hyoscyamus to the teaspoonful, it is evident that the lady took 240 grains of chloral that day, and possibly some more besides from the fourth bottle He has seen one other case of the bromidia habit The wife of a physician in an adjoining city came to him to be operated on for a cancer of the breast Upon examination of the breast no cancer was found, and he decided that the trouble was neuralgia, which view was afterwards concurred in by Dr Gross, of Philadelphia, whom the lady went to consult Upon her return from Philadelphia she came once more under his care The husband of the lady had warned him not to give her hypnotics during his treatment, so he assiduously avoided this class of drugs He was informed, however, by one of the ladies in the same boarding house, that his patient was in the habit of taking bromidia in considerable quantities She, however, never showed the effects of it, and he was unable to say how much she took Her husband soon took her home

It is probable that the effect of the chloral in the first case was heightened by the depressing action of the bromide of potassium He desires to enter his strong protest against prescribing proprietary medicines in general, and bromidia in particular Such mixtures should be kept by the druggists under lock and key, and if sold at all it should be only on the prescription of a physician

DR G L MAGRUDER reported a case in which a woman who had formed the alcohol habit had found solace from that in bromidia When he saw her she had been taking it for some time, and was exceedingly depressed and incoherent in her speech It took several days to recover her from this state, and during that time she had to be most carefully watched as she used all sorts of subterfuges to get more bromidia Three days ago a lawyer came to consult him about his throat The gentleman had not been sleeping well and had been using bromidia, which he had obtained without a prescription He has himself given up the use of all such things for the past ten years

DR S C BUSEY said that he had never prescribed bromidia, but he has seen the effects of it He was called to attend a lady for whom bromidia had been prescribed for sleeplessness She took 3 drachms the first night and slept well The second night the same dose had had no hypnotic effect, but on the next day she was maniacal, which condition, however, did not last long The prescription called for ℥j every three hours until relieved He has also had other patients tell him that they were taking it occasionally, but they showed no ill effects from it The other day a leading druggist told him that there was more bromidia being used than anything else in that line Its composition, and even the name of the manufacturer, is unknown, and there is no guarantee that it contains what is professed

DR G N ACKER said that a year ago he was treating a man for nervous depression The patient had been an opium eater and an inebriate, and he had attended him after several of his debauches When first seen this last time he was apparently in a state of *mania a potu* He discovered that the man had taken several 2 ounce bottles of bromidia in the past three days Luckily, vomiting had prevented him from keeping it all down, or he would probably have been killed He was finally relieved, but not without much anxiety and trouble He thinks there should be some law to prevent the indiscriminate selling of such mixtures, just as there is about selling poisons He has, however, had some good results from bromidia

---

CHICAGO MEDICAL SOCIETY

Stated Meeting, May 2, 1887

THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

DR JOHN BARTLETT presented a

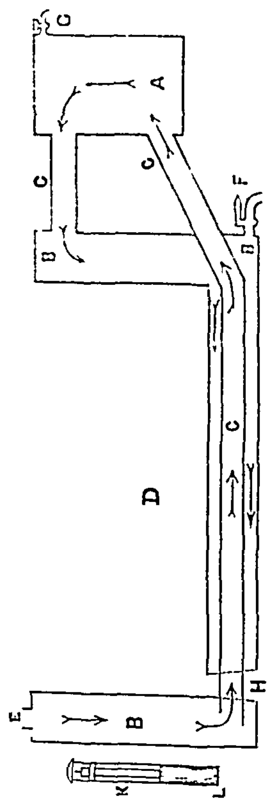
WARMING CRIB

It consists of an outer case of galvanized iron, or preferably of copper, and an inner smaller one Between the two cases is the water area, closed in all around Standing off some inches from the outer box is a small boiler connected by tubes with the water space The upper tube terminates immediately after entering the water area The lower one extends through the lower portion of the water space, to end near the opposite side of the box This is necessary in order to form an effective thermo syphon by means of which circulation of the water in the water space may be maintained, and thus an equable temperature of all parts of the crib

Leakage into the cradle-space might prove fatal to the occupant Against such an accident a safety vent is provided A conical tube is set, with the larger orifice downward, in the bottom of the crib space To prevent the ingress of cold air it is packed lightly with absorbent cotton If water gets into the cradle space it would run into the vent, wet the cotton, and cause it to fall out of the tube, leaving this free to act as a drain

One of the necessary attachments to such an ap-

paratus is a thermometer frame To determine the temperature of the water by the thermometer, without this attachment, is very unsatisfactory The column of mercury falls so rapidly upon removing the instrument from the water that it is impossible in this way to read the temperature accurately To obviate this difficulty, the expedient has been resorted to of placing the thermometer in a frame work of metal, so that the bulb and lower part of the stem of the instrument rest in a cup When the frame and thermometer are removed, the hot water brought up in the cup causes the mercury to retain its level and it may be easily noted



WARMING CRIB

A—boiler B—water space CC—thermo syphon tubes D—cradle space E—inlet F—outlet G—water guage H—safety vent K—thermometer frame with cup at 'L'

MEASUREMENTS FOR SMALLER CRIB RECOMMENDED

Outside measurement of crib (the figures have reference to the metal case) 26x26 inches outside depth 11½ inches size of cradle space 21x21 inches depth of cradle space 9 inches width of water space 2½ inches boiler 5 inches in diameter and 7½ inches long Pipes 1⅛ inches in diameter Safety vent 1⅛ inches at top at bottom 1⅝ inches Capacity of water space 12 gallons Distance of the boiler from the crib wall 5inches

MEASUREMENTS OF THE LARGER CRIB EXHIBITED

Outside measurement, 30x32 inches outside depth 14 inches size of cradle space 22x24 inches depth of cradle space 10 inches width of water space 4 inches Boiler 5 inches in diameter 9½ inches long Pipes 1¼ inches in diameter Safety vent 1¼ inches at the top, at bottom 1⅞ inches Capacity of water space 30 gallons Distance of the boiler from the crib wall 5 inches

NOTE —In arranging the bottom board and castors the carpenter should see to it, that the boiler stands at the proper height to accommodate the lamp to be used The Florence Lamp renders good service

It is desirable to encase the metal box with wood, both to retain the heat and secure additional strength The metal walls are not strong enough properly to sustain the pressure of a column of water ten inches high They bulge in all directions, indicating considerable strain at their seams The upward pressure on the bottom of cradle space in this incubator is 200 pounds The outer bottom and sides are therefore sustained by boards, and upward pressure upon the cradle space bottom is opposed by wooden standards, resting upon the ends of cross strips fitted to this bottom and held down by slats crossing from side to side over the top of the box

To use the apparatus, the water space is filled with warm water, preferably by means of rubber tubing, and the lamp lighted The water is never changed, and no attention is required further than to so adjust the wick of the lamp as to maintain the bed of the infant at the temperature desired With a little practice the flame of the lamp can be so adjusted by the eye, and the temperature of the incubator wall so estimated by the hand, that it will hardly be found necessary to consult the thermometer A given temperature of the infant's bed may be maintained within a few degrees with very little trouble The volume of water is so large that variations of temperature of the room, or in the amount of heat applied, are slow to induce a change in the temperature of the bed In this one a temperature of 92 degrees was generally maintained It varied between 92 and 86 degrees It was gradually allowed to fall to the latter point during a number of days preceding the final removal of the infant from the cradle A temperature of 122 degrees in the water indicated 92 degrees in the bed, the air of the room being at 70 degrees The gas stove or lamp used under the boiler should be capable of furnishing an abundance of heat, for the large crib here shown a coal oil lamp with a four-inch wick was amply sufficient It is convenient to have two of these lamps, so that one may always be ready when needed The bed is probably best made of horse hair or cotton, it fills up about one-half the cradle space The babe, dressed as usual, is covered by a woolen cloth, and over this rests a blanket sufficiently large to cover the whole top of the incubator, and thus to roof in the cradle space, except about the face of the infant

The incubator may be emptied of water by means of tubing attached to the discharge cock

DR DE LASKIE MILLER hardly thought it important to spend much time in commenting upon the couveuse after the description by Dr Bartlett It is an invention that is used successfully abroad, but he was not aware that it was used in Chicago The principles upon which it is constructed are manifest and important, the uniform temperature and the artificial feeding that is a part of the system in rearing feeble infants, are most important These two principles combined have in other places reduced the period of viability considerably, it is affirmed

DR F E WAXHAM had always used the hot water rubber bag in place of the incubator, using an ordinary basket well padded The rubber bag is then filled one-half or two thirds full of warm water and placed beneath the bedding If the water is replaced every three or four hours we can keep up a uniform

and satisfactory temperature This incubator possesses many advantages over the rubber bag, yet the rubber bag is quite convenient and can always be readily obtained

DR F C HOTZ read a paper entitled

THREE CASES OF SYMPATHETIC OPHTHALMIA ARRESTED BY EARLY ENUCLEATION OF THE INJURED EYE

(which will be published in a later issue)

DR CHARLES T PARKES reported two cases of

EXCISION OF CERVICAL GLANDS

One was in a child five years of age, the other in a child of twelve In the first case the mass was on the right side, the glands extending from the ear to the clavicle, there was no portion of the neck unoccupied by more or less of these glands In the boy of twelve it was even worse, as the photograph shows the glands extended beyond the midline of the neck posteriorly The trachea was carried two inches to the right of the midline by these tumors They interfered with inspiration, and failing to influence them by medical treatment they were subjected to operation and the glands all removed I have seventy-five of these glands which were removed from the boy of twelve years As far as the removal of the cervical gland is concerned it is a very simple operation to remove one gland if it is superficially situated, but when the deeper layer of glands are implicated, glands that are as extensive as these were, it makes a formidable operation In the latter operation there was not a blood vessel or a nerve in the neck below the parotid gland that could not be seen It was a very extensive operation, the most formidable that I ever attempted to do in anything of this kind The child lost a good deal of blood, notwithstanding the greatest of care In both cases, after the first incision, the knife was laid aside and not used at all unless necessary The incision was made over the most prominent part of the tumor and the mass laid open to view at once, subsequently the tumors were removed by scissors, keeping close to the growth It is a very easy thing to remove a superficial tumor, but it is difficult to safely remove these deeper tumors as they lie along the deeper vessels and in no instance should any tension be made on the tumor The capsule should be exposed to view and the tumor picked out of its bed slowly Dr Van Buren, in his late "Surgery," in the chapter on hæmorrhage, gives a graphic description of the terrors a young man got into by pulling upon one of these tumors and touching the knife to it while tense The first case I operated upon early in March, the boy recovered without any difficulty whatever

DR CHRISTIAN FENGER In connection with the extirpation of glands of the neck I wish to make a few remarks, and show a patient It is not exactly because this is a case of the same character as Dr Parkes's, but it is more to point out the limits of the possibility of operation on the neck This case is one of

SECONDARY CARCINOMA FROM CANCER OF THE LOWER LIP,

which was removed in December, 1884 In April, 1885, he came to me with enlarged glands on both sides of the neck and no relapse *in loco*, consequently no tumor on the lip Those glands were removed on both sides in the carotid triangle On the right side there was invasion of the facial vein with a thrombus about half an inch long, consequently that vein was ligated below the thrombus, between the thrombus and the jugular, before removing the tumor The invasion of a vein by any of the malignant tumors is a very grave complication, as we always expect a relapse In May, 1886, there was a tumor felt on the right side, the same side on which the facial vein had been invaded This tumor was about the size of a walnut when I removed it It had invaded the jugular vein so that an inch and a half to two inches of the jugular vein was removed It is natural that I should consider the case to be a hopeless one, as far as relapse is concerned, even after primary healing of the wounds, but, to my astonishment, the patient is well and there is no relapse anywhere The neck is everywhere perfectly free, and it is one year since the last operation Before the beginning of the second year after an operation for carcinoma most of them have relapsed, according to the statistics of von Winiwarter, 82 per cent relapse within the first quarter of the year, the relapses getting very rare in the second year Thus, when there is no relapse at the end of one year, we commence to consider the patient safe When we have to deal with malignant tumors on the neck there is a certain limit to operating which we cannot very well pass over

I will show a photograph of another case which represents the other side of the limit It was a carcinoma, not secondary but primary, in the lymph glands of the carotid triangle, or perhaps an alveolar sarcoma, I was not able to make a diagnosis The tumor was in the carotid region and was about the size of an orange, somewhat movable from side to side, and not from above downwards In these tumors there is a certain amount of immobility that will decide the surgeon beforehand to decline operating But the amount of immobility is somewhat disputed, as Konig and Friedel and others who have written monographs on operations in the neck state that, even if we have a tumor that feels rather immobile, we find that when we get down more and more, the tumor that seemed immovable from the beginning gets more movable and finally can be got out In the extirpation of this tumor not only the jugular vein was invaded (it was ligated double and removed) but the sheath of the common carotid artery was invaded There was no carcinomatous tissue, however, in the wall of the artery itself You will remember that the artery has a sheath separate from the common sheath, around the artery and the vein The artery was laid bare to the extent of over an inch on its outward surface The patient had on the third day a slight hæmorrhage, which was not reported, as it was thought it was unimportant, and five or six hours afterwards he had a final hæmorrhage which took only about a minute The microscopic examination of the wall of the carotid showed that there was no invasion of carcinoma tissue, but near to the place where the tumor had invaded the sheath

there was an island of granulation tissue in the intima, and this was the place where the artery ruptured As to the limits of the possibility of operating, I should put it where the malignant tumor has passed through the vein (which we can always remove with safety providing we keep our wounds aseptic) and into the sheath of the artery Here we meet with the danger of secondary hæmorrhage, and have to resort to ligature of the common carotid, which in itself is a dangerous operation

DR C T PARRIS It has been said with reference to these cervical glands, by a surgeon of good reputation, that it is always proper to do a surgical operation on them, because if you take out a few of the big ones the little ones get frightened and go away That has not been my experience, unless you get out all of the chain of glands that are implicated, the smaller ones are sure to enlarge rapidly soon after the operation I have several cases in my notebook, one an old man on whom I operated about six months ago The tumor was of immense size It was sarcomatous, and among other tissues the glosso pharyngeal nerve was divided, the digastricus muscle was torn off, and the lower half of the parotid gland removed under the supposition that it was a part of the tumor, and the facial nerve partly divided That man recovered It is not an unusual thing for a patient to recover from these operations on tumors in the neck It is my belief that a surgeon is not justified in operating on any of them where it is a malignant growth, or of such degree of malignancy that all the tissues are implicated in it, where the mass is fixed and immovable, because the patient will die either from the operation or the action of the disease If the attachments of the tumor can be pretty well defined, although immovable, certainly if *free and incapsulated, it makes very little* difference, because the records show that nearly all the important tissues of the neck have been divided in these operations, sections of veins, arteries and nerves made, without death following The cases related were merely instances of cervical glands

(To be concluded)

NEW INSTRUMENTS.

THE SURGEON'S PUMP

BY W J HERDMAN, M D,
PROFESSOR OF PATHOLOGICAL ANATOMY IN THE UNIVERSITY OF MICHIGAN

Seldom has the ingenuity of the inventor brought to the aid of the physician and surgeon a more useful instrument than that designed and manufactured by Mr E E Allen, of Grand Rapids, Mich, and named by him the "Surgeon's Pump" It combines the requisites of simplicity and efficiency in so evident a manner, and is so generally applicable to conditions arising in a great variety of disordered states of the system, that upon seeing it in operation one is disposed to smile at his own stupidity in not having thought of it himself

The invention consists of a rubber tube a yard or more in length, upon which a single loop is formed near the middle, and this loop enclosed in a circular wooden or metal box (Fig 1) Upon the inner sur-

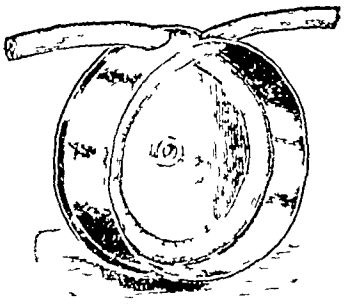


Figure 1

face of this loop a rubber roller attached to a crank is made to revolve, and the pressure upon this roller can be increased or diminished by a suitable arrangement of springs (Fig 2)

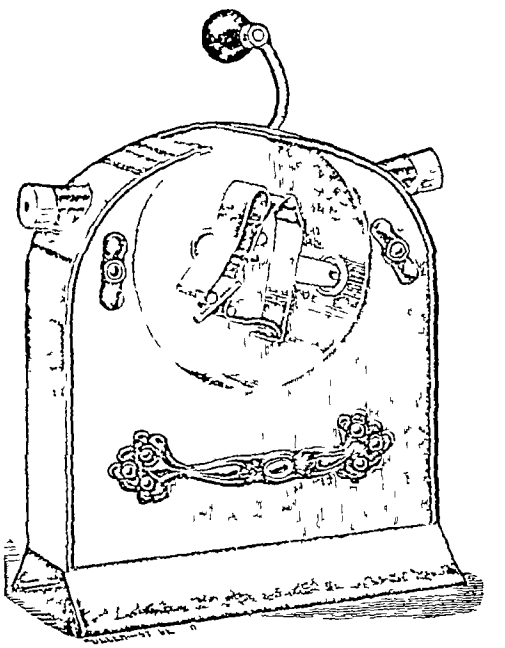

Figure 2

The range of application of this simple device, as will be seen at a glance, is almost unlimited where the necessity arises for withdrawing fluids from, or introducing fluids into, the body for any purpose whatever The suction and propelling power of which the instrument is capable would scarcely be credited by any one who has not seen it in actual operation, while the range of this power is all the way from nothing up to the extent of raising a column of mercury to the height of twenty eight inches simply by increasing the amount of pressure made by the rubber roller upon the coil of tubing The rapidity and steadiness of the current is wholly under the control of the hand moving the crank, while the current can be reversed at any moment Thus by suitable attachments to the extremities of the tubes this simple appliance may be made to serve the purposes of a syringe, an aspirator, a dilator, a douche, a blood transfuser, an air pump or a stomach pump

As a transfusion apparatus the instrument was first brought to my attention by Mr Allen some months ago, and it was for this purpose it was originally designed, and in meeting the conditions necessary for the ready transmission of blood from the veins of one body to another it is, as far as I am aware, far superior to any other instrument ever employed for this purpose It superiority consists (1) in the unimpeded and uninterrupted flow that can be established between the veins of giver and receiver, without any obstruction of valves or churning action of a bulb compressor, and (2) in the readiness and convenience of regulating the force and rapidity of the blood current by the proper management of the crank By means of it (3) the blood can be transmitted directly from the veins of one individual to that of another without the necessity of subjecting it to defibrination or any change or preparation whatsoever Of this fact I have abundantly satisfied myself by actual experiments upon animals in the presence of many witnesses, and the experiments of a like nature which Mr Allen has himself conducted in the presence of many able physicians, has established this fact beyond all questions If these experiments are properly conducted the coagulation of the blood, which would naturally be looked for upon the inner surface of the rubber tube, during its passage through it, does not take place, and all the constituents of the blood to the extent of 20 or 30 ounces are transferred without any change that has proved injurious to the animals receiving it

The proper temperature of the blood *in transitu* is maintained by surrounding the coil of rubber tubing with a water chamber, in which the water can be heated to the required degree

A very ingenious contrivance has been designed by Mr Allen, as shown in Fig 3, for placing over the

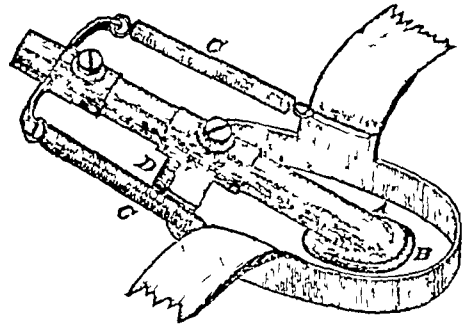

Figure 3

opening in the vein of the giver, and which avoids the necessity of introducing a tube within the vein in order to withdraw the blood, and thus one danger of phlebitis is obviated

As an aspirator this apparatus has the advantage of great range of suction power which can be readily increased and diminished as circumstances require, combined with the unparalleled convenience of a reverse action, which enables the operator to clear his needle from obstructing coagula or debris, or to wash out the cavity or abscess thus evacuated with a suitable antiseptic solution, without any other change than dipping the free extremity of the tube into the fluid to be injected and reversing the motion of the crank In cavities where considerable debris has collected and needs to be removed, as in cold abscesses, or the sediment remaining in the bladder after a calculus has been crushed a sudden suction force can be brought to bear upon such collection, and its removal be readily accomplished by introducing a wash bottle into the circuit of the tube and by a suitable shut-off, creating a partial vacuum in this bottle, and then suddenly opening its connections with the cavity containing the sediment to be removed, by which means such sediment is promptly sucked into the wash bottle through the catheter, canula or aspirating needle, that was introduced into the cavity No method so far devised for the removal of crushed urinary, caluli, or debris accumulated in other cavities of the body, or in abscess cavities, is equal in simplicity or efficiency to this

As a douche for irrigating the nasal, aural, vaginal or other passages of the body, this instrument is chiefly superior in possessing no valves to get out of order, and in the gentleness and steadiness of the current which it causes No injurious force of current is possible with it

As a stomach pump it is, as can be readily seen from its reversible action, much more serviceable than any now in use, since the stomach can be both emptied and again filled as often as thought necessary, by simply reversing the motion of the crank, and changing the free end of the tube from the jar containing the ejected fluid to that containing the injecting solution

As a dilator attached to distensible rubber balls, balloons or tubes, it has a field of usefulness in overcoming strictures, dilating passages and arresting hæmorrhages by compressing the bleeding walls of hollow organs, that will at once be recognized by the experienced practitioner Here either air or fluid may be employed as the distending agent

I have no mercenary motive in seeking to make known the usefulness of this invention In its manufacture or sale I am in no way interested

Box 91, Ann Arbor, Michigan

FOREIGN CORRESPONDENCE

STRASSBURG AND STUTTGART[1]

Kaberlé, his Methods, Treatment of the Abdominal Wound — Burckhardt — Stab wound of the Liver — Stab wound of the Stomach — Extirpation of the Larynx — Empyema of Frontal Sinuses — Antisepsis in Stuttgart Hospitals — Tuberculosis of Bone, Joints and Lymphatics — Peritoneal Sarcoma or Tuberculosis? — Osteotomy for Genu Valgum and Varum

Dear Dr Fenger —One of the most interesting men in Strassburg is Dr Kœberlé He is 65 years of age, and until recently lived the life of a bachelor in his comfortable and luxuriously furnished house opposite the Allerheiligen Hospital His young and beautiful wife has done her share towards his rejuvenation, and the climax of happiness culminated in the Kœberlé family on the appearance of an heir to the fame and fortune of the distinguished laparoto-

[1] By permission of Drs Fenger and Senn

mist For nearly half a century this faithful worker knew no pleasure outside of his profession, laboring faithfully in the interest of science and for the welfare of his fellow men, and is therefore entitled to the sunshine and happiness incident to a happy home, surrounded by his accomplished loving wife, and the innocent smiles of the prattling babe, certainly the most appropriate rewards this side of eternal bliss for a well-spent life Dr Kœberlé is a genuine Frenchman, who only makes use of his imperfect knowledge of the German language where no other alternative remains I met with a very kind reception, and spent a whole afternoon in his company at his house and in the Allerheiligen Hospital He answered my numerous questions willingly and fully, thus affording me a full insight into his methods of operating

From what I heard and read I am satisfied that he deserves to be called the inventor of the hæmostatic forceps, which in text books and catalogues are credited to his former intimate friend and now bitter enemy—Péan Kœberlé informed me that he had not used a ligature in his practice for the last twenty years Although he recognizes the importance of antiseptic precautions, he relies on thorough cleanliness, and only uses a solution of carbolic acid for his instruments That he is a believer in germs is evident from his practice, as he disinfects his hæmostatic forceps in the flame of an alcoholic lamp before every operation The hands are thoroughly cleansed with warm water and soap, and subsequently washed in a 4 per cent solution of carbolic acid He never uses a sponge, but relies entirely on pieces of dry cloth rendered aseptic by boiling The operating room is heated only to a comfortable temperature, as he believes the danger attributed to loss of heat during laparotomy has been greatly over rated For suturing material he uses ordinary Chinese silk, which before the operation is immersed in a 4 per cent solution of carbolic acid In tying the pedicle of an ovarian tumor he makes transfixion with an ordinary dissecting forceps, which is used in passing the double ligature In hysterectomy he resorts to two of his serre nœuds in controlling hæmorrhage, a tunnel is made through the centre of the pedicle with a blunt instrument and each side is compressed with an instrument, which are allowed to remain in the wound Great stress is laid upon the importance of not using these instruments as retaining measures, they must remain loose in the wound, as otherwise the wire would cut through prematurely He never resorts to protection of the abdominal contents, when protrusion has taken place, by compresses, cloths, etc, as he claims that microbes in the cloth might lodge upon the organ thus brought in contact, and produce infection

You will be interested to hear how Kœberlé treats the abdominal wound, he never includes the peritoneum in the sutures The sutures are passed down to but not through the peritoneum, nor do they embrace the skin The silk sutures are not cut short, the ends of two or more are twisted into a string, and are brought out of the wound, serving the purpose of a drain By disposing of the sutures in this manner he claims that he avoids the formation of parietal abscesses The skin is brought together with pin sutures The whole dressing is composed of a dry cloth compress and linen bandage The superficial sutures are removed after 24 to 48 hours, and further coaptation is secured by means of his favorite dry suture, made of strings of linen thread, which are twisted into a string on one side, while the other looks like a fan, which is fastened to the skin with collodion diluted with alcohol and ether Opposite points are tied together, and, as I had an opportunity to observe in two cases, served an admirable purpose in keeping the margins of the wound in accurate contact The deep sutures usually come away spontaneously after eight days He has never observed a ventral hernia after abdominal section in wounds treated by his method

Kœberle's supply of instruments is exceedingly limited, and after an inspection of his whole supply I could not but admire the man who can cope successfully with the most difficult cases with so few instruments Two small cases, containing perhaps two dozen of his favorite forceps, a few scalpels, scissors, hooks, anatomical forceps, and the indispensable serre nœuds, constituted the whole armamentarium chirurgicum Although I should not be willing to adopt all of his precepts, I am willing to confess that during my interview with him I had seen and heard many things which afforded food for serious thought Kœberlé is an original thinker, a fearless operator, and must be ranked foremost among the surgeons who are the recognized pioneers of abdominal surgery

During my trip I have been frequently impressed with the fact that some of the best surgical work is done outside of university towns Men whose names seldom if ever appear in surgical literature are doing excellent work, and it is to be regretted that the results of their observation and experience often fails to go on record, and thus science is deprived of a useful source of information A teacher who has to devote several hours a day to his classes cannot devote so much time to his patients or for reading and scientific research as a surgeon who only does hospital work and private practice Some of the best work I have seen has been by men who have charge of 100 to 120 surgical patients in some provincial hospital Most of these surgeons have at the same time a large and often remunerative private practice For instance, Medicinalrath Burckhardt, of Stuttgart, controls nearly all of the surgery in that rich and prosperous city and vicinity, and at the same time he has charge of the surgical wards in both hospitals He is one of the busiest men on the Continent, and knows how to make use of his advantages and opportunities The position of influence and eminence which he now occupies has been acquired in a remarkably short time, as he is not more than 40 years of age He is a thorough scholar, and familiar with current surgical literature His father is an old and respected physician in Wildbad The material which is at the disposal of Dr Burckhardt is immense, and represents every possible variety of injuries and surgical diseases, as I had an excellent

opportunity to verify during the two days I spent with him in his hospitals He is a very careful but bold operator, and a splendid diagnostician

About a year ago a man who had been stabbed in the abdomen was brought into the hospital The location and direction of the penetrating wound indicated that the liver or stomach was injured, and as the patient presented all the symptoms of acute anæmia it was evident that some large vessel had been injured Percussion proved that the peritoneal cavity contained a large amount of blood The patient was nearly pulseless, and it was apparent that unless hæmorrhage could be corrected death would soon follow Abdominal section was performed, and as soon as the abdomen was opened it was found that free bleeding continued from a large wound in the left lobe of the liver A rapid exploration showed that no other serious visceral wounds were present, and he turned his attention to arrest the flow of venous blood The usual hæmostatic measures for arresting hæmorrhage were out of the question, and it was finally decided to resort to the iodoform gauze tampon The entire track of the wound was firmly packed with several pieces of iodoform gauze and the end of the tampon was brought out of the abdominal wound to serve as a drain The abdominal cavity was cleansed as thoroughly as could be done under the urgent circumstances, and the wound closed, with the exception of an opening for the capillary drain Against all expectations the patient soon rallied from the collapsed condition, and recovered permanently without any further untoward symptoms For a long time a fistulous communication existed with the visceral wound The canal was dilated with laminaria tents and a piece of iodoform gauze removed from the depth of the wound After this the tract closed [1] In my address on "The Present Status of Abdominal Surgery," I suggested a somewhat similar treatment for visceral wounds of the liver, and the result of direct treatment of such wounds by abdominal section is certainly well illustrated by this case, and should stimulate others to adopt the same treatment in a class of cases which heretofore, on the expectant plan of treatment, has furnished a mortality of nearly 100 per cent

In the Katharinen Hospital I was shown an exceedingly interesting case in which abdominal section proved a life-saving measure for another class of visceral injury A circus rider, 30 years of age, had partaken freely of food and beer and soon after received a stab wound of the abdomen He was at once conveyed to the hospital, where he arrived in a dying condition It was ascertained that the abdominal cavity contained a large amount of fluid The opinion prevailed that the patient would die, and his ante-mortem statement concerning the quarrel was taken by an officer of the law The external wound was located to the left of the rectus abdominis muscle, and about two fingers' breadth below the costal arch From the location of the wound and its probable course it was surmised that the dilated stomach had been punctured With the consent of the patient the abdomen was opened from the wound in a downward direction to the extent of six inches The peritoneal cavity was filled with blood-clots, which were removed with the hand and sponges As soon as the stomach was brought into view a wound large enough to admit the tip of the index finger was found near the large curvature Hæmorrhage was freely taking place and required several catgut ligatures for its arrest The wound was closed with two rows of sutures Cleansing of the abdominal cavity was only imperfectly done, as it was feared that in the collapsed condition of the patient any further loss of time might prove fatal, and the local and general conditions appeared to preclude any possibility of ultimate recovery To the astonishment of all concerned, reaction commenced soon after the operation was completed, and on the third day the patient insisted on getting out of bed, as he had no pain or discomfort in the abdomen It is now sixteen days since the injury was inflicted, and the abdominal wound is closed, the appetite is good, action of bowels normal, no tympanitis, no pain As the patient insisted on leaving the hospital to day, permission was granted, however only after explaining to him that any ill consequences following such imprudence would rest exclusively upon the responsibility of the patient himself To all of these conditions he consented freely, and left the hospital a happy man and in the firm hope that in a few days more he would be in a condition to entertain the circus going citizens of Stuttgart

I had an opportunity to examine two patients who had recently undergone extirpation of the larynx In both cases the larynx was the primary seat of carcinoma, and as in neither case metastatic deposits in adjacent lymphatic glands had taken place, they were both considered as favorable cases for the operation One of the patients was a man 65 years of age, who was attacked with pneumonia on the second day after the operation, but is now recovering from the complication The second case was a woman of about the same age, who recovered from the operation without any untoward symptoms, but where the introduction of food without the œsophageal tube has proved very difficult, and where, in order to facilitate this process, a second operation was performed a day or two ago having in view the closure of the space between the open trachea and the anterior wall of the œsophagus Burckhardt prefers Hahn's sponge canula to Freudelenburg's instrument in all cases where the trachea requires plugging during an operation In two cases of empyæma of the frontal sinus I saw Burckhardt perform catheterization from nasal cavity with a delicate curved tube through which medicated solutions are injected

In both hospitals strict antiseptic precautions are observed For disinfection of hands spirits of turpentine is used Instruments are immersed in a five per cent solution of carbolic acid As an antiseptic solution corrosive sublimate is preferred Pads of antiseptic gauze and cushions of sublimated wood-wool are used in dressing wounds Most of the operations are performed in the Katherinen Hospital, where the operating room is located in a pavilion

[1] This case was described in THE JOURNAL, Vol viii, p 323

which is completely isolated from the main building Most of the surgical patients here live in barracks

Tuberculosis of bone, joints and lymphatic glands, as well as localized tubercular lesions in other accessible organs, are submitted to energetic use of the knife and sharp spoon, and it is claimed that since the practice of Bardenheuer, of Cologne, is imitated, the results have become more satisfactory

Among the more important operations that I witnessed here are the following A woman 30 years of age, who was delivered during the month of June last year, had suffered during the last months of her pregnancy from pelvic pains, which at times were quite severe She has not been well since Menstruation has ceased entirely She is somewhat emaciated, and at times the thermometer indicates a rise in temperature A physical examination reveals the existence of hard, irregular masses in the regions of both ovaries and broad ligaments It was impossible to make a positive differential diagnosis between pyosalpinx, tuberculosis and sarcoma, although the last condition was suspected A diagnostitial laparotomy was made to determine the character of the lesion and to proceed at once to operative measures, should the local conditions warrant such a course As soon as the abdominal cavity was opened the omentum presented itself in the wound, studded with small tumors the size of a millet seed to that of a pea, and the parietal peritoneum, when inspected, showed the same appearances No fluid in the peritoneal cavity The uterus appeared fixed by the masses on each side The diagnosis made was sarcoma, and the exploratory incision was closed Although I have implicit confidence in the correctness of the diagnosis *post incisionem* of Burckhardt, I could not resist the temptation to view the local product as a tubercular lesion, a suspicion which I based upon the history of the case, the symmetrical appearances of the masses in the pelvis on both sides, commencing in the region of the Fallopian tubes, and the extensive diffusion of the process along the peritoneal surfaces, as well as occasional rises in temperature One of the characteristic conditions of peritoneal tuberculosis—localized ascites, however was not present, but, as far as my observation goes, ascites is as much a symptom of peritoneal sarcoma as of peritoneal tuberculosis, and is not necessarily present in either of these conditions

At the last meeting of the German Congress of Surgeons numerous cases of peritoneal tuberculosis were reported as cured by simple exploratory incisions, and if my suspicions in this case should prove correct, and the same favorable termination should follow, my friend Dr Burckhardt will be the first to acknowledge his mistake In this connection I wish to express my doubts in regard to the correctness of the diagnosis in the many cases of peritoneal tuberculosis which have been reported as cured by such a simple measure as an exploratory incision I have no doubt in my own mind that many of these cases were not tuberculosis, but localized, non specific, simple peritonitis from which the patients would have recovered without incision, by simple rest I am strongly in favor of treating localized intra peritoneal tuberculosis by surgical measures, but in all such cases I should not be content until I had resorted to some measures directed toward the local condition, and having in view the complete or partial removal of the primary focus, and sterilization of remaining depots by the application of appropriate anti bacillary agents

In performing osteotomy for genu valgum and genu varum, Burckhardt does not perform the operation subcutaneously, but resorts to a free incision down to the bone, incises and reflects the periosteum at the point of section, and cuts the bone with a chisel sufficiently so that the balance can be readily fractured Before Esmarch's constrictor is removed all visible vessels which have been divided are tied, a small drain introduced and the wound sutured, an antiseptic gauze dressing applied and the limb bandaged upon a posterior tin splint The first dressing is changed after twenty four hours and the limb redressed in a similar manner The second dressing is removed in a week, when immobilization is secured by the application of a plaster of Paris bandage, or by weight and pulley and lateral support For one who is as familiar with the antiseptic treatment of wounds as Dr Burckhardt it may be perfectly safe to transform a subcutaneous into an open fracture, but for others less skilful or conscientious, the subcutaneous section of the bone deserves preference, inasmuch as experience has shown that, with ordinary care, injury to important organs can be prevented N SENN

BOOK REVIEWS

ANÆMIA By FREDERICK P HENRY, M D, Prof of Clinical Medicine in the Philadelphia Polyclinic, etc, etc Reprinted from *The Polyclinic* Sm 8vo, pp 136 Philadelphia P Blakiston, Son & Co, 1887

The want of a trustworthy guide in the field—or to many, the wilderness—which this little book covers has long been felt, especially in this country This book is the first systematic treatise on anæmia published in America, and embodies the results of years of study by a thoroughly competent worker It is not a compilation, but is based upon personal observations and accepted physiological and pathological facts The book is by no means so small as it may appear, for no words are wasted It includes Methods of Examination, Anæmia in general, Exciting Cauaes of Anæmia, Symptoms of Anæmia, Anatomical Characters, Diagnosis, Prognosis, Treatment of Anæmia in general, Varieties of Anæmia, Chlorosis, Anæmia of Puberty, Anæmia Lymphatica, Leucocythæmia, Anæmia Splenica, Pernicious Anæmia, Secondary Anæmia, Toxanæmia, Parasitic Anæmia Perhaps it would have been better had a more particular explanation been given of the various methods of examining blood, especially as the larger works dealing with this subject are by no means so clear as they should be The book is to be recommended in the most unqualified manner

MISCELLANEOUS.

LONG ISLAND COLLEGE HOSPITAL —During the spring term which closed the first week in June, the students had the opportunity of attending two cases of abortion and seventeen cases of labor in the new maternity wards of the hospital

CONTRIBUTION TO THE CONGRESS FUND —Since writing the editorial paragraph calling attention to recent contributions to the fund for the International Medical Congress, we learn that the Missouri Medical Association has contributed $300, and the St Louis Medical Society $200, for this purpose

JUBILEE MEDICAL HONORS —Dr Garrod, Mr G H MacLeod, of Edinburgh, and Dr Aitken were made Knights on the occasion of the Queen's Jubilee Dr James Alexander Grant, of Ottawa, was made Knight Commander of the Order of St Michael and St George There were ten other appointments and promotions of medical men

VIENNA PASTE IN DETERMINING ACTUAL AND APPARENT DEATH —Among the means of determining between actual and apparent death, says the *Medical Register*, M Peyraud regards cauterization of the skin by Vienna paste as one of the most certain In the living subject the eschar formed will be of a reddish black or brownish color, while in the cadaver it is yellow and transparent If the eschar is formed slowly, and is of a yellow color, the subject is dead, but if it is red, brown, or black, it may be assumed that life is not yet extinct

MISSISSIPPI VALLEY MEDICAL ASSOCIATION —The next annual meeting of this Association will be held at Crab Orchard Springs, Kentucky, commencing July 13, and lasting three days The attendance promises to be very large and the papers very interesting Among special topics for discussion will be "The Modern Treatment of Phthisis," "Intubation vs Tracheotomy," "Brain Surgery," "Abdominal Surgery," "Must the Ovaries Go?" besides others of importance The Society requires the same qualifications for membership as the American Medical Association

THE VETERINARY PROFESSION AND PUBLIC HEALTH —A well known veterinary surgeon has, in a letter to *The Times*, protested against certain recent statements calculated to reflect on the attitude of the veterinary profession towards the scientific study of animal diseases which are related to the health of man We are convinced that it would be unfair to attack the whole profession because certain of its members have recently appeared less willing to value scientific observation than we think should have been the case As matter of fact, however, diseases of the lower animals have hitherto been considered rather in relation to their effect upon these animals than to the health of man For this no possible blame can attach to veterinarians, it has been necessary in the first instance for the importance of these maladies to be recognized, but we are sure, now that some have assumed unexpected prominence, they will meet with all the consideration they deserve The scientific study of disease, whether of man or of the lower animals, has become more possible during the last few years, owing to the better opportunities which exist for its investigation, and a more definite knowledge is now expected than heretofore No public health department is complete without the aid of those skilled in animal diseases, and we anticipate the need for services of this kind will not less stimulate the inquiries of veterinary surgeons than it has members of our own profession It is not many years ago that human infectious diseases were not properly differentiated, it will probably not be long before those of animals are as well understood as are now human maladies of this kind With the possibilities of experimental inquiry which are open to the veterinary profession, it may, indeed, be expected that the knowledge of animal diseases will soon be more precise than that of human maladies —*Lancet*, June 25, 1887

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JUNE 25, 1887, TO JULY 1 1887

Col Chas Sutherland, Surgeon, granted one month's leave of absence, with permission to apply for an extension of one month S O 126, Div of the Atlantic, June 23 1887

Lieut Col A K Smith, Surgeon, will be relieved from duty at West Point, N Y, on September 30, 1887, instead of on August 28, 1887 S O 144, A G O, June 23, 1887

Major J C McKee, Surgeon, granted three days leave S O 149, A G O, June 19, 1887

Major C H Alden, Surgeon, leave of absence extended to include September 29, 1887 S O 144, A G O, June 23, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING JULY 2 1887

P A Surgeon C W Deane, ordered to the Naval Rendezvous, San Francisco, Cal

Asst Surgeon H N T Harris, ordered to the Naval Hospital, Mare Island, Cal

Medical Director A C Gorgas, remain on present duty until December 31, 1887

Medical Inspector C J Cleborne, remain on present duty until December 31, 1887

Surgeon Benj F Mackey, remain on present duty until December 31, 1887

Medical Director J Mills Browne, will remain on present duty as member of Retiring Board until June 30, 1888

Medical Director Richard C Deane, will remain on present duty as member of Retiring Board until June 30, 1888

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING JUNE 25, 1887

P A Surgeon John Guiteras, detailed for temporary duty at Key West, Fla June 23, 1887

P A Surgeon Eugene Wasdin, relieved from duty at Marine Hospital, New York, N Y, ordered to Marine Hospital, Chicago, Ill June 23, 1887

Asst Surgeon Seaton Norman, to proceed to Charleston, S C, for temporary duty June 23, 1887

Asst Surgeon F C Heath, relieved from duty at Chicago, Ill June 23, 1887

ADDRESSES

ADDRESS IN DENTAL AND ORAL SURGERY

Delivered at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY JOHN S MARSHALL, M D,

CHAIRMAN OF THE SECTION ON DENTAL AND ORAL SURGERY, CHICAGO, ILL

The year which has just closed has been one of steady advancement in the department of Dental and Oral Surgery, though I am unable to report any particularly new discoveries or brilliant achievements

The investigations in the etiology of dental caries by Drs Miller, of Berlin, Mills and Underwood, of London, and Black and others of our own country are still being pursued by these gentlemen, but no recent important announcements have been made The opinion that the disease is caused by micro organisms developed in the mouth is, however, rapidly gaining ground, for the conclusions reached by these investigators point very strongly in that direction

A great deal has also been written during the year upon the treatment of pyorrhœa alveolaris, but very little has been added to the knowledge we already possessed of its etiology The most notable improvement in methods of treatment is that introduced by Dr Adair This consists in applying to the roots of the teeth, after the concretions have been removed, a saturated solution of iodine in wood creasote, and then filling the pockets with tannic acid dissolved in glycerine, to form a protective dressing, and repeating this treatment once each day until the pockets are closed by new tissue A method very similar to this was introduced by Dr W H Atkinson some twenty years ago, and which at first met with very general adoption, but soon fell into disuse

Since the introduction of Dr Adair's remedies many have called to mind those of Dr Atkinson, which consisted of four formulas, viz

1 Chloride of zinc and resublimed iodine, equal parts rubbed together

2 Saturated solution of iodine in alcohol

3 Saturated solution of iodine in wood creasote

4 Pure wood creasote Later he substituted caustic potash and crystalized carbolic acid, rubbed to a paste in a warm mortar, and which are now being used with much better success than formerly, doubtless owing to the fact that the disease itself is better understood, and consequently the remedies needed for its successful treatment

New instruments for various purposes and of unique forms have been invented almost without number, consequently we cannot take space to enumerate them Some are real improvements over the forms already in general use, but the greater number are of no real practical value, except to furnish employment for the instrument makers

The subject which has seemed to occupy the minds of the dental practitioners more perhaps than any other, has been that of *pulpless teeth* and their treatment Not that there has been any change in the mode of treatment, for this seems to be as nearly perfect as it is possible with our present knowledge to make it, but rather because they have been called upon, by one of our leading medical journals, to defend their practice The journal in question condemned the practice of treating and retaining in the jaws teeth which were diseased or dead, upon evidence, which to the dental specialist at least, seemed very meager, indeed, and then drew the conclusion, that as a result of such practice, "nervous diseases about the head were becoming alarmingly common[1]" While the editor in the same number of the journal calls attention to the article from which the above is quoted, and says it "furnishes additional evidence of the perils of tooth saving" These articles immediately brought out several vigorous protests from the dentists, but the discussion of the subject was cut short by the editor, as it doubtless seemed likely too become too voluminous for the pages of his journal But the vital question as to whether *dead teeth* could be retained in the jaws, be made useful and at the same time inoffensive to the general health of the individual, did not receive the attention that its importance would seem to deserve. The term *dead teeth* is usually applied to teeth which from disease or traumatism have lost the vitality of their pulps, and not in its broader sense, for that would imply also a loss of vitality in the cementum and the pericementum Teeth in this condition would give rise to irritation and acute inflammatory processes of the surrounding tissues, and like all irritating foreign substances be soon expelled from the economy

The term *pulpless teeth*—one in common use among dentists—better describes the condition of the teeth under discussion, and hereafter when referring

[1] Medical Record, Vol 26 No 14 page 374
[2] Idem 379

to this condition I shall confine myself to the use of this term The teeth, as is usually understood, receive their nutrition and sensation from two distinct sources, viz through the pulp which fills the central canal, and the pericementum which covers the root The pulp is largely composed of blood vessels and nerve fibres, which are continuations of the maxillary arteries and nerves, while the blood vessels and nerve-fibres of the pericementum, with the exception of a few small twigs from the above mentioned sources, are derived entirely from the gingival arteries and nerves

The pupil gives vitality to the dentine and the enamel, which makes up about four-fifths of the bulk of the tooth, but which contains only from 13 to 18 per cent of organic matter when taken together The pericementum, gives vitality to the remaining portion, viz the cementum, which is analagous to bone and contains from 30 to 40 per cent of organic material, and it is through the pericementum that the teeth have their attachment to the alveolus

The death of the pulp *per se* has no effect upon the functions or vitality of the cementum or the pericementum, for their is no direct communication between them, and experience teaches that these tissues may perform their office in a normal manner for an indefinite period after the destruction of the pulp, provided the dentine has been treated antiseptically, and the central canal hermetically closed at the apex of the root

In advanced life there is a tendency to obliteration of the pulp by peripheral calcification, a process similar to, if not identical with, the formation of the dentine Many times the pulp will be found reduced to a mere thread, and in others the bulbous portion is entirely calcified The functions of the pulp in these cases are more or less impaired or destroyed, but no discernible effect is produced, either upon functions of the cementum or the pericementum

There is, however, a form of calcification of the pulp known as interstitial, in which nodules of secondary dentine or osteo dentine are formed in the body of the organ, which frequently gives rise to severe neuralgia of the face and head, and reflex irritations resulting in diseases of the eyes and ears

In the articles referred to, the cases cited to substantiate the conclusions at which the authors arrived, presented no satisfactory evidence that would indicate the teeth as pulpless, or that they were the seat of alveolar abscess or pericementitis, in fact, the evidence was strongly in favor of the supposition that the reflex irritation mentioned, was caused by an irritated and inflamed condition of the pulps, the result of an advanced stage of caries The question which very naturally arose in the minds of all intelligent dental practitioners who had carefully read the articles, was whether the gentlemen who criticized the methods of treatment pursued by dentists in the treatment of pulpless or diseased teeth, and which has been the means of saving thousands and tens of thousands of teeth in a useful condition, some for ten, twenty, thirty, and even forty years, without detriment to the general health were competent to criticize, and whether after all they really knew the difference between a simple case of pulpitis and one of pericementitis, or anything whatever of their symptomalogy

There is no doubt that teeth which are diseased from alveolar abscess, (the result of the death of the pulp) accumulations of salivary calculus about the necks and roots, pericementitis or irritation and inflammation of the pulp from caries, etc, occasionally give rise to acute neuralgias of the head and face, and reflex nervous irritation, resulting in functional derangements and organic diseases of the eyes and ears, but that this is by any means common I do not believe, nor is the radical treatment insisted upon by these writers, viz, the extraction of all suspicious teeth, the only or best treatment to be recommended, for the greater proportion of such cases are amenable to scientific treatment The dentist who would practice such wholesale and ruthless destruction of the teeth would not be worthy the name of dentist, for it would be contrary to the natural impulses of humanity and against all sound surgical principles The educated dentist has been taught that it is his mission to *save* and not to *destroy* the teeth, and all his energies are brought to bear in this direction, while extraction is to be practiced as a *dernier ressort*

Pulpless teeth which have been treated by removing the devitalized or putrescing pulp, the central canal and the canaliculi of the dentine rendered antiseptic, the apical foramen hermetically plugged with an indestructible and non irritating material and the canal and cavity of decay properly filled, will, in nine cases out of ten, give rise to no untoward symptoms, and remain in the jaws indefinitely in a serviceable condition, the truth of which no doubt can be vouched for from personal experience by many gentlemen of the Association It occasionally happens, however, that a pulpless tooth, from the small size of its central canal or a sharp curvature of its root, cannot be successfully treated in the manner described, these will in many instances, sooner or later, give trouble from alveolar abscess, but because a few unfavorable cases can not be treated with success is not a good reason for discarding the treatment

Inflammatory conditions of the pulp, especially the subacute and chronic forms, very much oftener result in facial neuralgia and reflex troubles of the eyes and ears, than do pulpless teeth which have been treated by the method just described, "although no appreciable irritation may be experienced by the patient in the affected tooth[3]" Such cases can be cured just as readily and permanently by the devitalization of the pulp, followed by the usual treatment for pulpless teeth, as by the heroic measure of extraction, and be infinitely better for the patient A sufficient number of cases might be presented, gathered from the published records, to satisfy any fair minded member of the Association of the truth of these statements, but the time at my disposal will not permit me to do so

One of the authors of the articles referred to "re-

[3] Medical Record, Vol xxvi, page 525

gards the treatment of pulpless teeth by the practice in vogue, as the reverse of procedures founded on well established surgical principles, since the stopping of the natural outlet for the escape of putrescing products from portions of the pulp left remaining in the canal, and dental canaliculi through the exterior part of the tooth itself make their passage into the tissues underneath unavoidable The diversion of the drainage must be of questionable propriety in many instances, since the tissues about the roots of the dead teeth are liable to become infiltrated with the products of decomposition, the absorption of which, when slowly formed, is much more liable to contaminate the system than the discharge of pus into the mouth from an alveolar abscess[1] The argument looks plausible, and if the statements upon which it is founded were correct, it would be unanswerable, but unfortunately for the writer and his theory they are not He speaks of closing "the natural outlet for the escape of putrescent products, etc" from the tooth Which is "the natural outlet" the apical foramen or the cavity of decay? I answer, that depends upon circumstances When there is no communication between the central canal and the cavity of decay the apical foramen is the *only* outlet, when the cavity of decay communicates with the central canal then the cavity of decay becomes the *natural* outlet Other things being equal an abscess left to itself always chooses the shortest and quickest route—the one offering the least resistance—to the point of outlet But it is the duty of the surgeon to cut short the process by giving exit to such accumulations of pus or putrescent material, wherever located, at the earliest possible moment, and thus shorten the period of suffering and remove the danger from septic poisoning The same obligation rests upon the dentist

When there is no communication between the cavity of decay and the central canal through which discharge can take place, gases are formed by the processes of decomposition, and septic material is forced through the only outlet, the apical foramen

The root of the tooth being imbedded in a bony alveolus and surrounded by the tissues of the face and mouth, septic products discharged at this point not only immediately set up inflammatory action, resulting in acute alveolar abscess, but from its location and the character of the tissues to be penetrated in seeking an outlet, several days are required to accomplish it, and this, unless operative measures are employed for its cure, soon becomes chronic and more or less constantly discharges as the case may be, either into the mouth, the antrum of Highmore, the nasal fossa, or through the external tissues of the face, and which not infrequently if left to run its course, terminates in other and more serious complications Such cases, however, can in a majority of instances, be *arrested* in their course, and in still a greater number *prevented* if taken in time, by giving exit to the contents of the pulp canal by simply drilling an opening into the canal through the cavity of decay, or other convenient location, and removing the septic material This is the treatment pursued by reputable dentists Is it a proceeding contrary to sound surgical principles?

When the apical foramen has been properly closed there is usually no more trouble with alveolar abscesses, for septic materials are prevented from coming in contact with the surrounding tissues Is such practice "the reverse of well established surgical principles?" I think not It is nature's own method of trying to prevent a recurrence of the disease, for it not infrequently happens that the apical foramen in pulpless teeth, after a time becomes completely closed by a deposition of secondary cementum, doubtless the result of this previous irritation of the pericemental membrane Can we go far astray when we follow such teaching? Are we not constantly trying to understand the processes by which nature restores a diseased organ to health, and the laws which govern them, that we may profit by the knowledge, and so shape our treatment as not to antagonize them, but rather prove helpful? This is what the dentist is trying to do by the method pursued in treating pulpless teeth This is not empiricism, but enlightened, rational practice

Furthermore, when the central canal has been thoroughly cleansed by removing the remains of the devitalized pulp, the apical foramen sealed, the cavity properly dried, the dentinal canaliculi rendered antiseptic by appropriate treatment, the central canal and cavity of decay so plugged as to exclude air and moisture, it is hardly possible for "products of decomposition to be formed in the canal or canaliculi, pass into the tissues beyond and be absorbed"

The antiseptics generally used are wood creasote, carbolic acid and bichloride of mercury, either of which will prevent decomposition, but when, as in this method of treatment, the effect of excluding the air and moisture is added to the power of the antiseptic remedy, it seems almost impossible for decomposition to take place It is admitted that in those cases which have not received appropriate treatment such conditions do exist, but even in these extraction is not called for, as it is yet possible to place a good proportion of these in a healthy condition

In behalf of our specialty, I, therefore, enter a most earnest protest against the principles set forth in these articles, in so far as they attempt to prejudice the profession against a line of treatment that has stood the test of time and proved so signally successful in the hands of dental practitioners, and hope the members of the Association will not be inclined to accept such conclusions as a final settlement of the question, but carefully investigate every case of disease of the eyes and the ears, and neuralgias of the head and face, in relation to the influence of pulpless and diseased teeth in producing such conditions, and instead of advising the immediate extraction of the suspected teeth, the patient be placed in the hands of a skillful dentist for appropriate treatment

If such practices could become general we should not be confronted with the statement, that as a result of the practice of dentists in treating pulpless teeth,

[1] Medical Record Vol xxvi page 525

"nervous diseases about the head were becoming alarmingly common" If the principles which underlie the practice of dentistry could be better understood by the general practitioner, there would be fewer people in the world with endentulous jaws, and consequently more people with robust digestions, for it is a lamentable fact that with many the value of the teeth in promoting the general health is greatly underestimated, and patients are advised to submit to the extraction of teeth that could be successfully cured of disease and made useful for years The only way in which this end can be accomplished is through the medical colleges This Association a few years ago recognized scientific dentistry as a department or specialty of medicine by the organization of a separate Section This has done much already to stimulate the young men entering the ranks of dentistry to take a full medical education, and is resulting in a demand for broader and more comprehensive teaching in the dental schools, of the sciences upon which rational medicine and surgery are based What is most needed, however, at the present time, in view of the subject presented in this address, is that the medical colleges of our country should each institute a Professorship, or Lectureship, on dental surgery, through which all future graduates shall receive at least a theoretical knowledge of dental and oral diseases and their treatment The possession of such knowledge would place the general practitioners in position to correctly advise their patients with regard to the care and treatment of their teeth, be the means of preventing a great amount of suffering to their patients and annoyance to themselves from inability to correctly diagnose such diseases, as well as to check the wholesale destruction of organs so necessary to the preservation of the functions of digestion and a robust condition of health

LECTURE ON SUBCUTANEOUS BLOOD-INJECTIONS, SALT WATER INFUSION, AND INTRAVENOUS TRANSFUSION[1]

BY PROF DR H VON ZIEMSSEN,
DIRECTOR OF THE MEDICAL CLINIC IN MUNICH

(*Concluded from page 39*)

The effect of simple addition of fluid after loss of blood, as in cholera, etc, has, according to observations made thus far, been very considerable, and we must therefore notice this important fact Hitherto transfusion has been used in by far the greater number of cases of severe hæmorrhage which threatened life It was assumed that death from hæmorrhage was due to the loss of the carriers of oxygen, and on this account transfusion was done But in place of this *physiological* reason for hæmorrhagic death, Goltz has now brought forth the *physical* reason, "the emptying of the pump works" (das Leergehen des Pumpwerkes), in which he teaches that the heart can only set the blood vessels in motion by a certain degree of tension in the vascular system Hence it is deficiency of fluid which causes death Accordingly, Kronecker and Sander showed by experiments on animals that death from hæmorrhage could be prevented by the timely transfusion of salt solution, and Schwarz and others showed that the same was true in man in threatened death from hæmorrhage Since then salt water transfusion has come generally into use, and has been much used by surgeons and gynecologists This is only another illustration of how much practical therapeutics is indebted to physiology

But there is one thing that, from Maydl's and Schramm's experiments, must not not be overlooked hæmorrhage may be such that transfusion may be demanded to prevent death Transfusion of salt solution may delay death, but cannot prevent it Besides the diminution of the amount of blood, we must also consider the supply of oxygen carriers, and in all cases in which salt water transfusion is made to prevent death from hæmorrhage, it is advisable to follow it with transfusion of blood as soon as the alarming symptoms of threatened death are past In these cases, also, subcutaneous blood injections, on account of their safety and ease, are always to be preferred to intravenous transfusion

In salt water transfusion in cholera the case is, of course, different Here it is first of all necessary to keep the blood in circulation, to keep it in rapid motion, while the lost serum is being replaced That subcutaneous injections fulfil these indications much more completely than intravenous transfusion is already sufficiently shown

Determinations of hæmoglobin have so much the greater value, it seems to me, because they give some explanation of the question, how subcutaneous blood injections act in regard to the amount of hæmoglobin on the addition of indifferent fluids In order to solve this question, salt solutions and then defibrinated homogeneous blood were injected into various anæmic persons I may give two instructive cases in the first only small quantities of salt solution and blood were injected, in the second considerable quantities of each were injected

Marie S, æt 24 Chlorosis of high grade, moderate oligocythæmia, considerable oligochromæmia
Nov 5, 5 30 p m Corpuscles 2,612,500 in ccm, hæmoglobin 24 88 p c
Nov 6 5 30 p m, hæmoglobin 25 59 p c
Nov 16, 5 30 p m, hæmoglobin 26 35 p c
Nov 17, 10 30 a m, hæmoglobin 26 35 p c
Nov 19, 10 15 a m, hæmoglobin 26 42 p c
Nov 19, 10 30 a m, injection (subcut) 100 ccm of 0 75 per cent salt solution
Nov 20, 6 p m, hæmoglobin 25 29 p c
Nov 21, 6 p m, hæmoglobin 26 35 p c
Nov 23, 7 p m, hæmoglobin 26 35 p c
Nov 25, 10 30 a m, hæmoglobin 25 7 p c
Nov 25, 11 a m, injection 50 ccm defibrinated blood
Nov 26, 5 p m, hæmoglobin 30 81 p c

Notwithstanding the small amounts of the fluids injected, the difference between the action of the salt solution and of the blood injection is very apparent After the infusion of 100 ccm of salt solution the hæmoglobin fell 1 13 per cent, and did not entirely reach its former height in the next five days After the blood injection it rose 5 10 per cent, and then gradually went down in the next few days

[1] Translated, by permission of author and publishers, from advance sheets, by Wm G Eggleston M D, of Chicago

Still more instructive is the next case, in which observations were made during a number of weeks, and determinations made of the hæmoglobin, number of corpuscles, and proportion of white to red corpuscles

Anna G, æt 16, was overworked in the past few months and became very weak, entered hospital on November 18 Father living and healthy, mother dead, but patient does not know of what disease Patient has had no illness other than scarlatina Anæmia of high grade, muscular system weakly developed, has never menstruated No organic disease, appetite good, weight 77 26 lbs Ordered complete rest in bed, nourishing diet

Nov 19, hæmoglobin 37 75 p c, corpuscles 2,443,000, white to red 1 122

It is seen from this case that the number of corpuscles and the percentage of hæmoglobin do not bear any constant relation to each other From the tabulated statement the difference in the amount of hæmoglobin after saltwater injection and blood injection is apparent As in the case of Marie S, we see in this case that, a few hours after the injection of the salt solution (250 ccm), the hæmoglobin sank 7 28 per cent, and that this difference was again made up within four days The number of red discs, on the other hand, seemed somewhat increased, and the number of white cells proportionately increased Meanwhile, nourishing food and rest in bed also had its influence The increase of hæmoglobin after each blood injection, as opposed to the decrease after the salt-water injection, is very striking, but not so much the increase of corpuscles, at least not after large injections, in which a considerable number of cells in the body certainly died It is possible, moreover, that the quality of the blood injected in this case played a peculiar part, and that the corpuscles from an old person—the blood of the first and second injections came from an apoplectic person 60 years old—are not so suitable for transplantation as those of a younger person—third injection That the capacity of the red corpuscles for transplantation is not the same in all persons is shown in the following case, because the patient was injected with the blood which remained after the third injection in the case of Anna G, and because here the number of red corpuscles showed a corresponding material increase

Sophie G, æt 19 Primary oligochromæmia and oligocythæmia, otherwise a healthy and strongly developed person

Dec 18, Hb 45 54 p c, corpuscles 3,100,000, white to red 1 253

Dec 29, IIb 49 3 p c , corpuscles 3,830,800 , white to red 1 281
Dec 29, Hb 51 05 p c

In this case the action of the blood injection appears in a very satisfactory light, and as the result of the third injection in the case of Anna G was equally satisfactory, it seems that the blood of the well nourished young man (who was "full blooded" and somewhat hypochondriacal), was especially suitable for transplantation

In the case of Anna G it was very clearly seen that in repeated injections of blood in the same region (thigh), with each injection the subcutaneous cellular tissue became more capable of absorption, so that the injection as well as the dissipation of the blood became easier The case also teaches to what degree renewal of the blood can be carried In this weak 16 year old girl, weighing 77 lbs , the blood weighed approximately 7 7 lbs In this case 350 ccm of blood, more than one tenth of the whole amount in the body, were injected at one time, and in three operations 600 ccm of blood, almost one fifth of the whole amount, were added The case still further teaches that good results do not depend upon the quantity injected, but that even such small quantities as 75 or 175 ccm may give excellent results, while they have the advantage of causing no reaction (with the exception of unavoidable pains at the seat of injection), and no fever Furthermore, the sites of injection are not painful except to direct pressure, if ice-bags be placed over the thigh for the first few days after the injections

As a matter of fact salt-water injections present fewer difficulties than blood injections, because the dissipation and absorption of the water in the connective tissue takes place with greater ease and rapidity For this operation the site of injection need not be changed so often, but 3 or 4 syringefuls (75–100 ccm) may be placed in one spot And the pain of the massage is so much less severe than that after blood injections that chloroform narcosis may be dispensed with if the patient be not very sensitive

The possibility of introducing large quantities of water subcutaneously was shown in 1884 by Cantani and his colleagues in Milan, Naples and Genoa during the cholera epidemic These authors carried out the idea of antagonizing the loss of water and its effect on the circulation by infusing water into the subcutaneous cellular tissue Cantani's pupils generally infused 1,000–1,500 ccm of alkaline salt water in the ileo-costal region by means of an irrigator The solution consisted of soda 3, distilled water 1,000 parts, and was injected at a temperature of 39° C With very low temperature of the extremities the fluid was injected at 40° C In a typhoid stage with very marked reaction 500–600 ccm were injected at a temperature of only 37 5° or 38° C , and with very high fever at a temperature of 37° C Samuels' recommendation that the injections be made in the neck should not be carried out, as the cases in which this was done died of œdema glottidis Massage was not made over the site of injection, and the large quantities of water were left to spontaneous absorption The results of this method of treatment were generally satisfactory, though very different, according to the nature of the individual case, the stage of the disease and of the epidemic Further investigations on this subject are necessary, especially as there is a possibility that drugs and alcohol, which cannot be absorbed by the stomach and intestines, might be mixed with the water to be injected

The apparatus needed for salt water injections is not complicated A good glass syringe with a long, not too narrow needle, and holding from 25 to 50 ccm , is sufficient for salt-water as for blood injections, and in time of cholera can be carried in the pocket, as well as the necessary quantities of sodium chloride (7 5 grams to 1 litre), which may be used without carbonate of soda All that is then necessary is good thoroughly boiled water, and the injection can be made without difficulty or loss of time

Just as useful is the hypodermatic salt water injection in dangerous hæmorrhage, or severe acute anæmia from other causes But in all such cases in which it was simply a matter of choice, I would certainly give preference to injections of blood, for the reasons already stated But in many cases a blood donor is not at hand, and we cannot always get a sufficient quantity of blood, and in dangerous cases it is always better to fulfil the first indication and feed the heart-pump After this blood injection may be made, once or oftener as necessary Nor is there any objection, after severe hæmorrhage, to follow up the blood injection immediately by one of salt-water, the quantity of the latter being proportioned to the amount of blood lost And if there be danger in delay there need be no hesitation in using simple boiled water for the injection, as this can always be had Every physician, and especially every obstetrician, should carry a large syringe for subcutaneous injections in his instrument case During and after labor the most acute hæmorrhages occur, and it is impossible to supply new fluid to the system more quickly and more simply than by the hypodermatic method

This procedure is very much simplified by the filtering properties of the subcutaneous cellular tissue, which render filtering of the water unnecessary If a small foreign body is in the water it will be arrested by the connective tissue, or by the lymphatics, and kept out of the circulation, whilst in intravenous injections everything in the water goes into the blood In the necessity and haste after severe hæmorrhage this is a very important matter If you had a severe case of post partum hæmorrhage in the country at night, would you wait to get distilled water and chemically pure salt from the apothecary in town, or for the assistants and necessary apparatus for intravenous transfusion? But if you know that you can inject the necessary quantity of boiled water, and thus obviate the immediate danger to life, you will be much better equipped for such emergencies And if you find it necessary afterwards to make blood injections, and it is often necessary after severe hæmorrhage, you have time enough to prepare everything, and especially to find a blood donor The same is

true in cases of dangerous hæmorrhage from the lungs, stomach and intestines Experience will show how far reaching is the effect of salt water injections in such cases It must be remembered, however, that injections of blood can probably never entirely compensate for loss in large hæmorrhage, and that they only avert immediate danger

Under what circumstances subcutaneous blood injections would be efficient in gas poisoning (with carbonic oxide, chloroform, sulphuretted hydrogen) after sufficient depletion, I cannot say, as I have not had any experience thus far At all events the subcutaneous injections offer as many chances as intravenous transfusion if a previous venesection has been made We know that many poisonous gases, especially carbonic dioxide, taken into the blood through the lungs, take possession of the hæmoglobin of the corpuscles, and render them incapable of taking up new oxygen As shown by Kuhne, Landois and others, in these cases the supply of fresh blood has a better effect when a corresponding amount of poisoned blood has been taken from the system than when this is not done But in all cases the *quantity* of new blood supplied is of the greatest importance, the more functionating oxygen carriers added the greater is the guarantee that life will be saved Now, the quantity of blood supplied can be much more easily regulated and increased by subcutaneous injections than by intravenous transfusion, as the injections can be repeated or discontinued according to the exigencies of the case Certainly the results of intravenous transfusion thus far in gas poisoning and other similar cases are not very favorable Heineke has collected 23 cases (mostly coal-gas poisoning) of which 14 were unfavorable in spite of transfusion, 8 favorable, and 1 uncertain But the experiments should not be discontinued, especially since we have the hypodermatic method

Transfusion of salt water has very recently come into use in poisoning Favorable results have been obtained from experiments on animals and men so far as can be seen, and give reason to think either that the addition of fluid to the blood may act favorably either by the dilution of the blood or by exciting the renal secretion Kocher transfused 200 grams of blood without result in two cases of iodoform poisoning, and then saved the patient by transfusing 500 ccm of salt water This result is certainly very good, but its value as proof is lessened by the previous transfusion of blood But in individual cases it should be remembered, in determining the selection of blood or salt water, that in those poisons which either deprive the corpuscles of their oxygen (carbonic oxide, etc) or act upon them as direct solvents and so cause hæmoglobinæmia and ferment intoxication (potassium chlorate, chloral phosphorus) transfusion of blood must be unhesitatingly given the preference over salt water

The action of blood infusion in acute infectious diseases has been but little studied Most of the experiments and observations have been in regard to septicæmia, and the results thus far have been very unsatisfactory, abatement of the infectious condition was probably obtained, but no permanent improvement, and the conclusion seemed almost inevitable that, in septicæmia at least, the addition of new blood was only pouring oil on fire, as the ferment thus received new material to work on, and the fire kindled anew This may be true of septicæmia, but I may doubt if this opinion is just for all infectious diseases and for all stages of infection For the present, at least, when according to our knowledge of the cyclical course of the infectious condition and the limited life duration of the germ ferment in individual infectious diseases, we may assume the cessation of activity of the microorganisms, and transfusion may perhaps be really useful under certain circumstances and in certain conditions (heart weakness in typhoid, etc) In cholera, at least, the necessity of infusion against the consequences of loss of water from the system has been rendered probable by the observations of the Italian physicians The future will show what is to be expected from the addition of new blood in the other acute infectious diseases In spite of the opinion that infusion of blood only adds new material to the infectious process our experiments should not be discontinued—as is shown by the change of opinion within a century regarding the diet of fever patients Theoretical ideas may sometimes be a serious hindrance to therapeutic progress

More trustworthy is transfusion in chronic infectious diseases, in the dyscrasiæ and anæmic conditions Our blood injections in chronic tuberculosis had a striking but transitory effect It is not impossible that by oft repeated addition of new blood to the oligæmic organism there may be a more permanent improvement in such hopeless cases, especially if there be no fever It is certainly worthy of trial In regard to scorbutus I have had one case, of a man, in which the disease was of the most severe type, and a fatal issue was supposed to be almost certain The usual antiscorbutic treatment and diet were carried out for 6 days without noticeable good result; and by an injection of 50 ccm of blood the hæmoglobin was raised in one day from 28 7 per cent to 33 94 per cent Three days later, when hæmoglobin had fallen to 32 2 per cent, 50 ccm of blood were again injected, and on the next day the hæmoglobin was 34 55 per cent While the increase in the hæmoglobin may seem small for the amount of blood injected (100 ccm), the improvement in the color, expression and strength of this patient was very striking There can be no question of the effect of good feeding in this case, as the result followed immediately upon the injection, and previous to this the most nourishing diet had accomplished nothing in 6 days The sudden change from a very grave condition to one of convalescence is to be ascribed to the blood injections alone

The chronic anæmias and dyshæmias, with their numerous functional troubles have been thus far but comparatively seldom submitted to the methods of blood renewal, at most the conditions thus treated have been leukæmia, pseudoleukæmia and pernicious anæmia The experiences in these severe forms of disease of the blood forming organs are certainly not very encouraging, though some cases have been very much improved

Pernicious anæmia is, of all others, the disease for often repeated transfusions This was impressed upon me by the case of a man, 45 years old He was in such a condition of anæmia that he was confined to his bed, becoming syncopal on rising Prof Heineke and I transfused 180 ccm of blood This was followed by a severe rigor and very high temperature, but from that time the appetite, sleep and strength rapidly improved, and the patient passed into a condition of tolerable existence He died two years later of recurrence of the disease, due to over-tax of strength by traveling

Pernicious anæmia would be a very favorable condition for repeated large hypodermic injections, such as were made in the cases of R C and Anna G In our ignorance of the nature of this form of disease, in the lack of sharper etiological indications, and in the face of the notorious inactivity of all dietetic and therapeutic measures, there is but little doubt, as in leukæmia and pseudoleukæmia, that the addition of new functionating blood must be favorable to the organism, and that this improvement need not always be merely transitory, but may perhaps be permanent, in so far that the anomalies in the functions of the blood forming organs, especially in the medullary canals of bones, possibly kept up by the anomalous condition of the blood, may be removed by the addition of new blood As analogous cases may be cited the favorable action of our repeated blood-injections in protracted severe chlorosis, which did not tolerate iron and were not improved by the most careful diet I am convinced that in these cases the hæmoglobin is not merely temporarily improved, but a cure may be obtained, possibly by action of the blood in a manner unknown to us

Most of the cases in which I have made subcutaneous injections were cases of severe chlorosis and chronic anæmia from different causes These cases are comparatively frequent, and remain under observation for some time, and it is very necessary to study the action of this procedure in female cases on account of the great frequency of such anomalies of the blood in women

Heineke, in his admirable work on "Bleeding, Transfusion, and Infusion," (Deutsche Chirurgie, Lief 18, 1885,) expresses the opinion that, in man at least, the greater part of the blood injected subcutaneously first disappears from the cellular tissue, and the blood cells break down and their coloring matter is changed into pigment scales Every one of my anatomical examinations of the site of injection, which I made one or two days after the injection, in phthisical and other patients, showed me that besides a slight hæmorrhagic imbibition of the cellular tissue there was no trace of the injection It may be true, as Heineke and Schaffer state, that in experiments on animals the greater part of the corpuscles lie (faded) in the tissue after several days, but in man, at least so far as my researches show, the statement is incorrect The enormous strengthening effect of an energetic massage is undervalued by Heineke, and the value of experiments on animals, for the solution of this question, over-rated as by Ehrlich If Heineke's opinion be correct would not an injection of 275 ccm of blood at one sitting cause hæmoglobinæmia and ferment intoxication, or at least fever and hæmoglobinuria? But in this case (R C[1]) there was no reaction at all, and to me this is better proof than everything else that the injected blood passed directly into the circulation without undergoing important histologico chemical changes At all events, experiments on guinea-pigs, in which energetic massage is impossible, do not weaken the positive and incontrovertible results of my cases

ORIGINAL ARTICLES.

TREATMENT OF FOUR CASES OF ACUTE TRAUMATIC TETANUS

Read in the Section on Surgery and Anatomy, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY R. C McCHORD, M D,

OF LEBANON, KY

In presenting for your consideration four cases of acute traumatic tetanus that have come under my observation and treatment, I feel that they are cases of no little interest, in view of the fact that three of the four cases recovered In searching the literature of tetanus, we are confronted with the overwhelming and prevalent idea that acute traumatic tetanus is incurable Dr Gross, in summing up his ideas as to the prognosis of traumatic tetanus, says "In an experience of forty years, I have seen but three cases where the patient escaped with his life, and then only after a protracted and painful struggle" M Nicaire, author of the article on "Injuries and Diseases of Nerves," in the "International Encyclopædia of Surgery," in speaking of the influence of treatment upon the termination of tetanus, says "Must we maintain the absolute distinction into two forms, the one acute, inevitably mortal, and the other chronic, which recovers by itself, and in which the sole part of therapeutists is to prevent death by asphyxia and give the patient ease? I believe it more correct to say, with Richolat, setting aside the overwhelming forms, which seem beyond the resources of art, that the acute form has never been directly cured"

Did time permit, I might go on and cite many similar opinions going to show how little faith the profession at large have in the therapeutic medication of tetanus My experience, though in a small way, has taught me to differ from the authorities, how wisely the difference of opinion may have been formed, from experience, I will leave you to judge We are all too much accustomed to folding our arms in the presence of these so called incurable diseases

Case 1—On June 23, 1878, H C, a stout negro man, aged 21, presented himself with a pistol ball under the skin of dorsal surface of index finger of left hand He stated that the night previous he was cleaning an old Colt's revolver, and by some means dropped the cylinder on the hearth, causing its dis-

[1] THE JOURNAL, July 9)

charge The ball entered the palmar surface of index finger, slightly touched the bone, and lodged as described on dorsal surface, without fracturing the bone Why it did not pass on out I cannot explain, except it was probably due to the defective or small charge of powder I made an incision and extracted the ball, dressed the finger, and saw no more of H C until five days later, when I was hurriedly sent for, with the message that he was having spasms On my arrival I found him in bed perfectly rigid with his head thrown backwards and the weight of body resting for the most part on back of head and heels The muscles of back and abdomen were rigidly contracted, as were also those of the extremities and jaws The wound on finger presented an unhealthy appearance, discharging a thin sanious fluid, and manifesting no disposition to heal, the whole hand being very much swollen Seeing that there was no disposition to a relaxation of the spasm, I began the administration of chloroform and continued it to its full effect, with the result of relaxing the rigidity of the muscles As soon as the spasm of muscles was controlled, I dissolved about 30 grains of bromide of potash in water, and waited for the effect of the chloroform to pass off sufficiently for him to swallow I forced him to swallow the potash, when he again soon became rigid as before The chloroform was again brought into use, with like result I sat by him for several hours, keeping him under the influence of the chloroform, for without it he was rigid I gave him about 90 grains of bromide of potash in about two hours, the relaxing effect of the chloroform enabling me to administer it

Under the influence of the chloroform and bromide of potash, after several hours, the opisthotonos and general tetanic spasms were to a slight extent controlled I left him in the hands of his friends for the night, after instructing them to administer the bromide of potash in 30 gr doses every two hours, and to keep the tetanic spasms under control with the chloroform I saw him the next morning and, to my surprise, he was some better, the muscular rigidity being relaxed His friends had carried out my instructions explicitly, and the amount of chloroform they had used told plainly how hard the tetanic spasms had been to keep under control

In order to test the full effects of the bromide of potash, I let him out from under the influence of the chloroform, but on attempting to give the bromide of potash, he became rigid, and I was forced to again resort to the chloroform before he could swallow I then began to give the bromide of potash almost without regard to quantity, all he could well swallow By evening the tetanic spasms were about under control, and he could take the potash without the aid of chloroform He was also able to swallow some fluid nourishment The same course of treatment was followed out during the second night, the chloroform rarely being necessarily used On the morning of the third day he was completely relaxed From this time on for ten days he was kept fully under the influence of the bromide, only once having to resort to the use of chloroform, and then it was only when the bromide of potash had been held up to test its effect His hand was dressed, for the most part, with a flaxseed poultice, and nourishment administered in the fluid form at regular intervals He made a complete recovery, without any unpleasant effects, so far as I could determine, from the heavy administration of the bromide

Case 2 —In the summer of 1879 T R, a negro boy aged about 10 years, stout and well nourished, trod on a rusty nail while at play, and about four or five days afterwards I was asked to see him for what was supposed to be sore throat When I saw him first nothing was said about the injury to foot from nail I found the muscles of jaws somewhat contracted, and on his attempting to open his mouth he complained of a cramping at angle of jaws and some pain I made a superficial examination and prescribed some domestic remedy The following day I was asked to see him again, as he was acting a little peculiar and could not open his mouth On attempting to force his mouth open, he complained of great pain and a sense of impending suffocation, which in a moment was accompanied by a look of contentment and then the sardonic laugh I soon recognized the trouble, and on inquiry was told that about six days previous he had trod on a rusty nail, and though the wound was painful at the time, yet it had never suppurated and was now healed over On examination I discovered, immediately under the instep and a little to the outer surface, a slight abrasion of the skin covered over by a slight scab On removing this I found the wound had not healed, but presented an unhealthy appearance While examining the wound his jaws became firmly closed, the muscles of neck contracted, and for a moment he was almost rigid I ordered bromide of potash in 10 gr doses every hour, and a poultice to the foot At my morning visit I was told that he had been able to take but little of the potash on account of the difficulty in swallowing By this time the tetanic spasms had become frequent and more prolonged, and it was impossible for him to swallow but very little fluid at a time I began the administration of chloroform as in *Case 1*, gave the bromide of potash while the muscles were relaxed by chloroform In this way he took the potash at intervals of one or two hours during the night The next morning the frequency and severity of the tetanic spasms were somewhat less, and he could swallow fluids without producing much spasm, though occasionally during the day and following night chloroform had to be administered to keep them under control On the morning of the third day the spasms were under control and the chloroform was no longer needed The bromide of potash was kept up at intervals of two hours for the next three days, during which time he took liquid nourishment with but little difficulty, the spasms gradually growing less frequent and severe, until finally they ceased, and on the morning of the sixth day from time of commencing the treatment he was in fine condition, free from spasm and but little rigidity of muscles Although I considered him almost out of danger, yet I ordered the potash continued Soon after my morning visit on the sixth day, I left town and was gone all day, and on my return late in the afternoon, I found a message awaiting me to go to

see the boy immediately On my arrival at the house I was surprised to find my patient dying He died soon afterwards On inquiry I learned from the mother that, soon after my morning visit, she discovered that the powders of bromide of potash were out She sent to my office to know whether she must have the box refilled with the powder or not, and as I was absent, instead of having it filled and continuing the medicine as directed, she concluded to wait until my return, with the result as stated

Case 3—April 15, 1881, I saw, with Dr W R Ragsdale, L B, a native of Germany, but of Jewish birth He was 17 years old, general physical condition delicate He had but a few weeks previous arrived in this country, and could speak but a few words of English Four or five days previous to my first visit he had accidentally pierced his left hand through with a paper-file, just external to the metacarpal bone of little finger The wound had not healed, but presented an unhealthy appearance, quite tender to the touch He presented well marked trismus at intervals, which gradually progressed until opisthotonus was well marked He was naturally very obstinate, and not being able either to speak or understand English, it was with the greatest difficulty that we could get him to take the medicine prescribed The wound was laid open and dressed with a poultice, which seemed to give him some ease, and, we flattered ourselves, some temporary relief to the tetanic spasm By direction of L B's uncle, who visited him, I was requested to remain in the case with Dr R, so that one or the other could be in constant attendance He complained of much pain at site of wound, for the relief of which hypodermics of morphine were given The tetanic spasms were controlled at first by chloroform Bromide of potash was administered in 20 and 30 grain doses every two hours For several days, while he took the potash without opposition, the spasms became less severe On account of his extreme repugnance to chloroform and determination not to take any more, hydrate of chloral was given in 20 grain doses every three or four hours as a substitute Sometimes it was administered by the mouth and at other times by rectum, as the caprices of our patient would allow It served its purpose well When we could get him to take the potash regularly the chloral was not required, only to produce sleep For nearly four weeks this patient was kept under the influence of bromide of potash, and I would say for three weeks he averaged 20 grains of bromide of potash every two hours This was found necessary to control the tetanic spasms Sometimes when his opposition to the potash was very great, we were compelled to forcibly hold him and administer a dose of chloral per rectum and wait until he was under its influence before he would take the bromide During the first two weeks chloral was given sometimes as often as four or five times in the twenty-four hours, to quiet excitement and produce sleep During the four weeks he was under treatment, he was systematically nourished with beef essence, milk, etc

When all symptoms of tetanus had passed away, we noticed that what appeared in this patient to be obstinacy at first, was now a true mania, it requiring the combined efforts of four or five men to restrain him This latter condition gradually subsided, and he was finally sent to the asylum, and is now there a hopeless imbecile

Case 4—On August 25, 1886, I saw Ben B, white, aged 8 years, stout and healthy He had just received a badly lacerated and contused wound of the fingers of the right hand, by its being caught in a forty knife cutting box The ring finger was cut through the bone in two places, the middle finger was cut through in three places, and in each place the finger only hung by the skin and a few tendons The index finger was lacerated, contused and broken, involving its second and third phalanx There was so little vitality in the injured portion of this finger that it was removed on the 29th, at its middle joint, four days after injury, simply by twisting it off with the forceps As there was not sufficient flesh to cover the bone, it was deemed best not to cut off the protruding bone, but leave it to be covered over by granulation After this all the wounds progressed quite favorably, those of the other two fingers, which I had brought together, sewed up and put on splints, healing to a great extent by first intention On September 6, twelve days after injury, my little patient visited me at my office to have his hand dressed, as usual The granulations had by this time covered over the end of bone and were quite luxuriant In directing a warm spray of carbolic acid on the granulating surface, for the purpose of cleansing the same, I noticed a peculiar expression of countenance and a sudden contraction of the flexor tendons of the arm He complained of slight pain at site of wound, and a stiffness of muscle of jaw, together with constricted feeling in throat and chest This lasted only a moment, accompanied by a look of contentment, or mild form of sardonic laugh I immediately recognized the trouble as being trismus, and on examining his pulse, found them quite frequent He was sent home and put to bed, and bromide of potash ordered in five grain doses every two hours

I informed his father of what I feared would be developed, and promised to call in the afternoon At my afternoon visit I found my little patient in bed with his jaws stiff, and at intervals of a few minutes they were locked tight, and a general rigidity of muscles of back and abdomen occurred I immediately advised amputation of the finger at its metacarpo-phalangeal joint His parents objected, and asked a postponement until next morning, which I very reluctantly consented to At eleven o'clock that night the father informed me that the tetanic spasms were getting more frequent and of greater severity, and asked me to see him On my arrival I found an increase both in frequency and severity of the tetanic spasms With the consent of the parents, I amputated the finger at its metacarpo-phalangeal articulation, dressed the wound, gave a hypodermic of morphine, and ordered bromide of potash in five grain doses every two hours

On the following day the tetanic spasms were less severe and of not so frequent occurrence The

bromide of potash was continued as before, and hydrate of chloral given to produce sleep For the next two days the spasms were light, though easily excited by noise or movement of body

On the third day after amputation the wound was dressed and found to have healed about one half by first intention The other portion looked well By the evening of the third day the tetanic spasms had gradually grown more severe and opisthotonus was well marked The potash was increased to 10 grains every two hours, and hydrate of chloral in 5 grain doses given at intervals varying from three to four hours, according to the degree of excitement, etc From this time on he took 10 grains of bromide of potash every two hours for three weeks, night and day, when it was gradually reduced in dose and given at greater intervals for two weeks more During all this time hydrate of chloral was given in 5 grain doses either by mouth or rectum, when very much excited or sleep was desired I think he had an average of four or five doses of chloral in every twenty four hours This boy had beef tea, milk, and soft boiled eggs at regular intervals during the whole period of sickness He was discharged on October 1st, well, having been under treatment for tetanus since Sept 6th He made a perfect recovery without any impairment of mind whatever, and is to day as bright a little fellow as one would wish to see

To summarize The first case was treated with bromide of potash and chloroform, recovered The second case with bromide of potash and chloroform, and although the mildest of the four cases, died, I think simply from neglect to keep up the administration of potash The third case was treated with chloroform, bromide of potash, and chloral, recovered physically, but mentally a wreck, whether the latter was due to the potash, or chloral, or not, I am not prepared to say The fourth case was treated by amputation, bromide of potash, and chloral, with perfect recovery in every respect

---

ESSENTIAL INDIVIDUAL HYGIENE OF A MUNICIPAL POLICE FORCE FOR THE PREVENTION OF PULMONARY DISEASES

BY GEORGE HOMAN, M D,

PROFESSOR OF HYGIENE ST LOUIS MEDICAL COLLEGE SECRETARY OF THE STATE BOARD OF HEALTH OF MISSOURI MEDICAL EXAMINER TO THE ST LOUIS POLICE DEPARTMENT

Read in the Section in State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

The following remarks are not intended to cover the whole field of personal prophylaxis against diseases by members of a municipal police force, but only to direct attention to certain facts that appear to be well established, and which have been observed by me in the two years last past, during which time I have performed the duties of Medical Examiner to the Police Department of the City of St Louis The particular matter to the importance of which I desire to call attention, is that of pulmonary hygiene, if it may be so termed, to certain statistics collected by me in regard thereto, and their obvious bearing and indications in the direction of measures to lessen disability and loss of service from avoidable forms of pulmonary diseases

In the course of my service in connection with the department, it became my duty during the summer of 1885, to make a careful physical examination of all members of the police force of this city below the rank of captain, numbering at that time 482 men The examination was made by order of the Board of Police Commissioners, the purpose being to ascertain as nearly as possible the exact bodily condition of each member, and to determine the degree of physical soundness and efficiency possessed by every officer examined at that time Careful measurements of chest dimensions were made in every instance, and every symptom and circumstance denoting pulmonary integrity or infirmity was recorded and duly considered in the final classifications, as to physical standing and ability made when the work of examination was completed

The average mean girth of chest at the level of one inch above the nipples of all the men examined, was found to be something above thirty-eight inches, (38 '1375)—the extremes being the greatest possible degree of respiratory expansion and contraction of the thoracic cavity upon forced inhalation and expiration The measurements in every case were taken with a steel line with all clothing removed from the upper half of the body The average degree of expansibility of the chest was found to be 2 759 inches, this measurement indicating the degree of mobility or extent of free play of the chest walls As correlative facts of interest in this connection, it may be stated that the average individual stature was 5 8 ' 22, the weight 167 36 pounds, and the average waist girth 34 131 inches

Examination of the mortality record of the department, and of the morbility returns of the force, so far as they were ascertainable, showed that among the causes of police disability pulmonary affections hold a leading position, and it has been my desire to ascertain, if possible, if there is any determinable relation between these potent forms of mischief and tax upon vitality and efficiency, and the routine duties of individual members, and the discipline and code of management under which the department is operated

The daily routine duty required of a patrolman in this city is twelve hours' service out of the twenty-four, extending from 11 o'clock A M or P M as the case may be, the change from day work to night work, and *vice versa* being made every three months Aside from one hour's drill per week in the manual of arms during the winter months, no bodily or athletic exercise is required of a policeman other than that involved in patrolling the district assigned to him, with the incidental exertions needed on his part to maintain law and order therein, the result being that there is usually plentiful foot and leg exercise to the neglect of other highly important parts of the body

The standing force comprises in its members many veterans, some twenty-six of whom have seen more

than twenty years of police service in connection with this department These veteran members, while now invalided to a great extent and exempted from any but the lightest duties, no doubt represent the survival of the better physical element of a contingent recruited under rather lax regulations as concerns inspection and physical qualifications, and, indeed, it may be said that at no time have the regulations governing appointments to the force been very stringent, or the requirements in this respect exacting

The mingling of the physical statistics of the aged, invalided and veteran elements with those of the healthy, younger and more vigorous men tends, of course, to deteriorate the statistical effective standing of the force as a whole, but, while this is necessary in order to a correct representation of existing facts, it may be said in mitigation of the effect on the showing thus made that 277 members, or over 57 per cent of the total force, have seen less than ten years' service, and 152, or over 31 per cent have been members less than five years, the total of those who have seen ten years' service and more being 205

The numerical and physical composition of the force naturally fluctuates somewhat through deaths, dismissals, and resignations, about six recruits a month on an average having been added during the last two years

In endeavoring to determine the special influence, if any, of police life and duty upon the pulmonary organs and functions, I have carefully compared the ascertained data in this respect of the regular members of the force and those added from time to time to fill vacancies in the ranks The average age of the men at the time of the department examination was a little over 38 years, while the average age of recruits is 28 years

In making good the losses of the force it is the usage of the Board of Commissioners to appoint the applicants for a probationary period of six months if he be found qualified after rigid physical examination for such appointment, the department being given the benefit of any doubt that may exist in the mind of the examiner After the expiration of the probationary term he is eligible to appointment as a regular member of the force Not infrequently before such appointment he is ordered up for a second examination, and it has been in such cases that I have been most forcibly impressed with the influence of police life and regulations in inducing tendencies to pulmonary weakening, and foreshadowings of pulmonic default and danger

I have already stated the average girth of chest, and thoracic expansion of St Louis policemen The same measurements of 122 recruits show in respect to the first dimension a difference in favor of the latter of about one quarter of an inch—and the average chest expansion of the latter being 3 "395 to 2 "759 in the regular policeman The averaged mean girth of chest in the recruit is 38 "354 to 38 "1375 of the patrolman—a difference not strikingly great and of much less serious import in the sense in which the matter is being now considered than is the former, as a considerable gain in mean chest girth may be noted while the absolute breathing capacity of the chest cavity, and free play of its walls are diminished —the increased girth being due to extra costal causes, usually to overlying fat, and for this reason deductions from a mere increase of measurement around the chest must be deceptive as an indication of soundness of the lungs, the ascertained degree of normal expansibility constituting the only decisive test so far as measurement is concerned

Additions to the regular force are usually made from among men employed as laborers, mechanics, porters, teamsters, and like occupations in which the muscles of the arms and associated parts are brought into more or less constant vigorous exercise Upon assignment to police duty the accustomed symmetrical use of all the working muscles is lost as compared with previous occupation, walking being all that is required of the officer, and the hurtful effect of the change, after the lapse of a few months even, upon pulmonary expansibility and capacity is most marked In repeated instances applicants for appointment coming from occupations requiring all-around exercise, and in whom the respiratory apparatus was found to be of superior excellence as regards both free expansibility and normal breathing sounds, after six months police service the normal expansion had decreased from one half to one inch, or even more, and the comparative rigidity of the chest walls was accompanied by impaired or roughened vesicular murmur, with symptoms of circumscribed congestions, incipient catarrhs, and other signs of sluggish pulmonic circulation,—the girth of the chest being usually not sensibly changed

This condition was so uniformly present in those cases in which the subject had resorted to no gymnastic exercise to maintain the initial good condition of the chest, as to at once attract my attention, and the good results that have followed the employment of means to increase the capacity of the chest, to develop and strengthen the auxiliary muscles of respiration, and to favor the free play, suppleness, and expansibility of the chest walls have been equally manifest These results have appeared not only in a betterment of chest measure, but in the appearance and establishment of normal respiratory sounds, in increased freedom from coughs and colds, in improved general circulation, in appetite, digestion, nutrition and excretion—in a word there was a general exaltation of physical vigor and power that was consciously felt and enjoyed by the subject

In instances where the applicant fell short of the standard through pulmonary defect remediable in character, the counsel given by me to overcome the difficulty has been followed for some months with the constant result of improvement in wind, and deepening of respiratory capacity The means recommended to this end have been the systematic judicious use of hand weights, sand bags, clubs, and other devices for symmetrical physical exercise and development found in gymnasiums

From all the foregoing considerations my opinion is, that the omission from the department equipment of means for regular systematic chest and arm exercise, and the enforcement of their use as a necessary

part of routine duty in any police force on a service basis similar to the one in this city, indicates a point of vital weakness, and that such lack constitutes an unguarded avenue by which a host of physical evils assail the municipal defenders of life and property A fair degree of speed with good wind endurance is recognized as being necessary physical qualifications of the perfect officer, and these requisites can only be secured by appropriate gymnastic drill designed to exercise and harmoniously develop and preserve the entire body

It is my deliberate conviction, reached after a careful study of the records of two years, together with other material data, that, aside from the natural decline of chest elasticity which accompanies advancing years, there is a certain percentage of loss in this respect in the police force of this city that may be justly ascribed directly to general physical conditions incidental to the performance of duty under existing regulations, and I believe that this loss represents a definite and calculable proportion of the total impairment of service by sickness in the force Furthermore, I believe that the cause of this waste and loss in vitality, time, and effective employment, bears a constant and definite relation to defects and errors of long standing in the physical regulation of the department—that this wastage is largely avoidable, and that the shrinkage or impairment of chest capacity, due to faulty physical conditions in the constitution of the department, means so much loss in time and so much loss in money which might be saved by a modification of discipline and the introduction of simple means for the attainment of the desired end The money loss to an employer from a case of pneumonia or pleurisy in an employé may be computed, and the relative cost to the possible effective police total of all forms of preventable lung maladies may be closely reckoned, and the value of the results of preventive medicine, or pulmonary hygiene, be determined on a financial basis For if, by a practicable modification of existing regulations and adjustment of means to ends, an average increase in breathing capacity of say one half of an inch per man could be secured to the entire force, it is my judgment that the loss of time from pulmonary troubles would be decreased at least one third, while the gain in general vigor, morale, and physical power would be not less than fifty per cent , and, certainly, the money equivalent of this gain would represent many hundred dollars annually, not to speak of the decreased amount of physical suffering, the increased ability to perform duty, and the prolongation of years of effective service to the veterans of the force

It is but simple justice to say that the efforts of the present Board of Police Commissioners have been uniformly directed toward the achievement of reforms which would include the ends herein suggested—to the correction of organic faults in the department, and to elevating the standard of physical vigor and efficiency of the police force of this city

---

EMBOLI—THE SEQUALÆ OF TWO CASES OF LABOR

BY W L SCHENCK, M D,
OF OSAGE CITY, KANSAS

Recognizing the advantages that arise from an interchange of opinions upon the etiological and pathological conditions and therapeutic results observed in our daily routine of practice, I take pleasure in reporting the following cases

On Sept 17, 1886, I was called to see Mrs C , æt 25, in consultation with Dr Artz She was a delicate little woman, but with fair general health, of English birth, and for five years a resident of Kansas She was living on a rolling prairie, half a mile from any other house, with all the surroundings healthful, excepting that the house was over crowded with occupants She and her husband occupied a good sized and well ventilated room, with a south and east front, which, however, was over crowded with various articles of furniture She had been delivered five days before of her first child The labor, though tedious, exhausting and followed by more than ordinary hæmorrhage, was in all respects normal The lochia was abundant, and there was no unusual tenderness in the genital organs She had slight fever and cough, with pain and dulness in the right side of the chest There was great anxiety and a nervousness that bordered on hysteria There had been no exposure and no imprudence in her management, unless it be considered imprudent to neglect some of the impossible directions laid down by some distinguished gynecologists

On Sept 22, I was called again to see Mrs C , and learned that after my former visit she had promptly developed lobar pneumonia of an asthenic type, involving about half the right lung

Oct 20 Was requested to take charge of the case, Dr A being sick The pulmonary inflammation had subsided, though there remained considerable cough and expectoration From continued recumbency she had developed serious and somewhat peculiar bed sores There was a slight abrasion about the middle of either nates, beneath and about which, extending down to the muscles and across the lower end of the sacrum, the tissues were dead and sloughing There was tenderness and enlargement of the crural vessels of the left leg, some pain in the popliteal space, and marked phlegmasia of the calf This condition was first noticed two days before

Nov 4 Though convalescing nicely from her former troubles and visits discontinued, I was called again to find her with inflammation of two thirds of the right breast, followed by small multiple abscesses There had been no exposure, the foot not having been placed on the floor since the occurrence of the phlegmasia

Nov 20, 1887 I was called to see Mrs S , a German woman, aged 37 years Having had eleven premature deliveries and no living children, she was far from being vigorous She was advanced 250 days in her twelfth pregnancy Had been confined to her bed eight days, and during that time had felt no motion No fœtal heart sounds recognizable Labor was progressing slowly, retarded by an un-

yielding cervix, and was completed in twelve hours The placenta was promptly expelled, but was followed by an active hæmorrhage that required a second injection of hot water to arrest it Antiseptic napkins were kept over the vulva, and the vagina washed out every twelve hours with a three per cent solution of carbolic acid The patient doing well, necessary directions were given and visits discontinued on the third day

Nov 29 Was recalled at 1 A M Found the patient, who had not been out of bed or exposed to any extraneous impression that would tend to local irritation or inflammation had been, without premonition, seized with intense pain in the right lung and pleura There was agonizing dyspnœa, superficial, hurried and anxious breathing, pulse feeble and rapid (150), and temperature 101°F The lochia was free and the generative organs in good condition A hypodermic injection of morphia, with elix val ammonia and hot jacket poultices gave relief She was treated *secundam artem* until Dec 8, when visits were discontinued

Dec 11 Was recalled to find the patient with phlegmasia dolens The calf of the left leg was irrecusably pinned to the bone, swollen and tender, with tenderness along the entire track of the crural vessels Treatment was prompt and there was a gradual subsidence of symptoms

Dec 18 Sent for in haste Found the patient suffering from severe pain and great tenderness in the region of the sigmoid flexure of the colon, with corresponding depression and disturbance in the circulation With hot fomentations, anodynes, stimulants and antiseptics the patient was relieved and made a favorable recovery

These cases are not reported for the purpose of detailing treatment, which was adapted to the symptoms and pathological expressions as apprehended, using such agents as carbonate of ammonia freely, sulphocarbonate of soda, sulp quinia, tr ferri chlorid, etc, but rather for speculation upon cause and pathology Coming near together and quite unique they were of more than ordinary interest

Whilst various causes, other than those consequent upon the sequalæ of labor may give rise to phlegmasia dolens, it is so largely a sequent of labor that we look to the conditions then present for its typical cause The decomposing contents of the uterus and vagina, through the denuded inner surface of the one and the abrasions in the other find ready ingress to the circulation, when they may give rise to such diseases as puerperal fever, or may cause embolism or thrombus, for, as Dr H Lee has shown by ample experiment, blood admixed with purulent matter will coagulate much sooner than when left without such admixture And so the experiments of Dr McKenzie demonstrated that the obstruction of the veins met with in phlegmasia may be excited by various unhealthy matters in the blood, and that its cause *is to be sought for in a vitiation* of the circulation rather than in injury, inflammation or other diseases of the veins Dr Tilbury Fox, in two papers read before the London Obstetrical Society in 1861, evolves as one of his conclusions "The rapid ingress of abnormal fluid suddenly and in large amount will cause instantaneous coagulation of blood, and that large drains from the system are followed by rapid and compensating absorption"

In labors associated with excessive hæmorrhage or other unusual sources of exhaustion, the uterine tissues are relaxed and there is profuse lochia with excess of decomposing detritus The depleted circulation takes up with avidity whatever is within its reach In the poisoned blood, consequent upon this, rapid osmosis is sufficient cause for the formation of coagula, either in the form of emboli or thrombi, which since the investigations of Virchow are considered the sufficient if not the sole cause of phlegmasia dolens But why should we confine the embolus or thrombus to the crural vein? If the morbid material inducing it enters the portal circulation it must go thence through the liver to the vena cava, through the right side of the heart into the pulmonary artery, through the lung to the left side of the heart, through the aorta to the distal extremity of the arterial circulation and through the capillaries of the leg to be returned as far as the crural vein, where, perhaps from pressure of the uterus or a loaded sigmoid flexure, or the narrowness of the crural ring, the passage of the blood is obstructed and a thrombus formed, either by the accumulation of emboli or by coagula forming on the venous walls While certain vessels, from location or construction may be specially liable to obstruction from thrombus or emboli, when the circulation receives those poisons that tend to coagulation can we with any certainty predicate where the burden will fall?

A much lamented President of the United States was shot by an assassin, standing six feet in his rear A No 42 conical ball, from an English bull dog pistol, went crashing through a floating rib, arrested only by its passage through the first lumbar vertabræ While Bliss and his associates, supposing it had been deflected from its course by the rib, an intercostal muscle, or perhaps the liver, and were locating it with their "plumbometer" in the right iliac region, the decomposing tissues burrowing along its track were manifesting their presence in distant parts of the body So when a circulation, poisoned with decomposing lochia, or other contamination shall presage embolus or thrombus there is no law whereby their lodgement shall be restricted to any given locality

A coagulum arrested in the crural vein may cause a phlegmasia and its peculiar milk white swelling from obstruction of the lymphatics, and the dolens or partial paralysis from pressure upon the nerves, and there may be crural phlebitis, but the emboli are not necessarily confined to the crural veins, and even when thrombus has occurred then it may be broken up into emboli that may manifest their presence in distant parts, just as cancer cells escaping from a cancer of the stomach may be arrested in the liver, or escaping thence be lodged in the capillary circulation of the pulmonary artery or elsewhere *So the* emboli consequent upon the causes of which I have spoken may be arrested in the liver, lung, mesentery, brain, mammary gland or crural vein

Austin Flint, "Practice of Medicine" p 78, says "The embolic changes, embraced under the name of infarctus, in the comprehensive sense of the term, are especially liable to occur in the spleen, kidneys, lungs, liver and brain, In the lungs small extravasations of blood, circumscribed gangrene, lobular pneumonia and little abscesses are local events attributable to pulmonary embolism"

In the cases reported we were unable to find other cause for the various lesions noted than a poisoned circulation ultimating in embolism If we are correct they are of unusual interest in illustrating the varied phenomena resulting from that cause The patients exhausted and depleted by previous disease, labor and uterine hæmorrhages, their excessive lochial discharges found ready admission to the circulation, causing the formation of emboli In both cases the emboli entered the right lung through the pulmonary artery and were lodged in its capillary distribution, ultimating in pneumonia. In both cases they collected in the crural vein producing thrombus and phlegmasia dolens, in one case inflammation and multiple abscess of the right mammary gland, and in the other embolism of the mesenteric gland

---

SYPHILIS, MARRIAGE, AND DIVORCE

Read before the Section of Practice of Medicine, Materia Medica and Physiology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY JOHN V SHOEMAKER, A M, M D,

OF PHILADELPHIA

The relation of syphilis to marriage is one of irreconcilable antagonism, and if the old maxim of "once syphilitic, always syphilitic," were true, the conscientious physician would be compelled to forever forbid matrimony to those who have been contaminated by the virus of syphilis Fortunately, however, syphilis is usually a curable, and in some cases a self limited disease, and when the system is no longer under its influence marriage is permissible, and even advisable

When can a person who has had syphilis marry without running the risk of transmitting the disease to his wife and children? Not until he is completely cured This is, of course, an indefinite reply, but no absolute rule can be made which will meet the indications of every case Each case must be studied by itself The age, habits and general condition of the patient, the character and duration of the attack, the nature and extent of the medicinal treatment, and the age and general condition of the other partner in the proposed matrimonial compact, must all be carefully considered

Syphilis, as a rule, is less severe, and shorter in duration, in the young and robust than in the old, and in those debilitated by anæmia, scrofula, malaria, anxiety, and alcoholic and other excesses The macular and papular varieties are indicative of a mild type of the disease, while the pustular, bullous and tubercular forms are evidences of its obstinacy and malignancy The character and amount of the medicinal treatment is also of importance in deciding the question There are various remedies which possess the power of abating the symptoms of the disease, but mercury and iodide of potassium are the only medicines which can eradicate the disease from the system, and even they must be given continuously or at intervals for a long period

The age and general condition of the other partner in the intended marriage must also be taken into consideration Extreme youth, anæmia, debility, or the existence of the strumous or tubercular diathesis, should be regarded as almost insuperable barriers Robust health, and young, adult age render the system less susceptible to insidious injurious influences

As a general rule, patients presenting a mild type of syphilis may be permitted to marry within two years or two years and a half after the time of infection, provided they have been under proper mercurial and restorative treatment for eighteen to twenty months, and have not manifested any symptoms of the disease, nor deterioration in general health, during the six or eight months immediately preceding marriage

The reappearance of the symptoms, or a decline in general health, is a contraindication for the marriage for another extended period

If the case has been of the malignant variety, characterized by the formation of large pustules, bullæ, tubercles, and rupial sores, medication should be continued for from two and a half to three years, and marriage not allowed for another year, and then only on condition that no suspicious symptoms manifest themselves in the meantime

Syphilis of the nervous system or of the viscera should preclude marriage for at least five years, during which specific treatment should be thoroughly but judiciously carried out

If syphilis of any variety unfortunately develop or be contracted after marriage, the utmost care should be taken to avoid communicating it to the innocent party Sexual relations should be suspended, and kissing and all other familiarities avoided until vigorous specific treatment has removed the lesions and annihilated the poison of the disease If these precautions be disregarded, and pregnancy unfortunately supervene or evidences of infection appear in the wife, she ought also be placed upon a decided specific and tonic plan of medication, or the most deplorable results will follow

Syphilis in Relation to Divorce—Public opinion has been so profoundly shocked by the scandalous facility with which divorces may be obtained in many States, that the tendency of future legislation will be to lessen rather than to increase the number of causes which are to be regarded as justifying a legal dissolution of the matrimonial bond Care should be taken, however, to prevent the reaction from becoming so extreme as to preclude the addition of salutary amendments to existing laws upon the subject The sanctity of the marriage contract is not attacked by indicating the various circumstances which impair its integrity Every civil and ecclesiastical code plainly sets forth a greater or less number of reasons which

either render the marriage contract absolutely null and void, or which justify its limited dissolution It would be folly, however, to claim that any particular code will be found sufficient for all ages and all nations Laws must be modified in accordance with the exigencies of the occasion and the habits, virtues, vices and necessities of the people for whom they are made, and the law of divorce is no exception At present, desertion, cruel treatment, adultery, and various bodily and mental defects are recognized to be so destructive of the peace and happiness characteristic of the true marriage state, that they are declared by law in all countries to justify, if not to necessitate, partial or complete divorce

There is a more dangerous and more insidious source of domestic misery, however, than any yet named Syphilis is more subversive of the objects of the matrimonial compact than all the offenses enumeerated upon the statute-book The principal object of marriage is the propagation of a healthy race Syphilis poisons the fountain of life at its source Marriage is presumed to be the bond of affection between two of the noblest of God's creatures Syphilis converts it into the shackle by which the living is chained to the loathsome dead The evils which the syphilitic husband entails upon his wife, his offspring and society at large, are so many as to almost defy enumeration

Is it not, then, right and proper that syphilis should be recognized as first among the causes which justify the innocent party in applying for divorce If may be objected that the provision relating to adultery as a basis for proceedings in divorce is sufficient to protect the interests of all concerned Sad experience, however, declares that it is not The proof of adultery is difficult, and sometimes impossible, to obtain, unless the guilty parties are caught *in flagrante delictu*, and in many cases the disease dates from before marriage The present active existence of syphilis, however, is readily ascertained It may be also objected that syphilis may be unwittingly or innocently contracted in the discharge of professional duties, and a hundred accidental ways, and that it would be exceedingly reprehensible to permit such an unfortunate occurrence to be used as a pretext for violating a sacred compact and exposing a blameless person to the derision of the world This objection is deserving of consideration, but any proposed law could be modified to meet it No man worthy of the name would insist upon the continuance of marital relations under such circumstances, and no true woman would insist upon partial or complete separation in such a case, unless compelled to do so for self protection He or she should however, be given the legal privilege to do so as a last resource

The famous Colin Campbell case proves that such an amendment of the law is necessary The plaintiff, Lord Colin Campbell, applied for an absolute decree of divorce from the defendant, his wife, Lady Mary Campbell, upon the ground of adultery and desertion The facts as developed by the trial were that, when Lord Colin was married, he was suffering from a complication of venereal disorders, and that as a result of his diseased condition, the consummation of the marriage was followed by a violent attack of metritis and perimetritis, which seriously prostrated the defendant After a tedious illness she recovered, but refused to permit a renewal of the marital relations The honorable Lord then determined to humiliate and disgrace her by accusing her of adultery and desertion and applying for a divorce, which he believed his rank and prestige would enable him to obtain at once Fortunately, however, Lady Mary Campbell had a host of friends who demanded that an exhaustive inquiry should be instituted before any decree would be made The testimony was published, and popular sympathy was manifested so strongly in behalf of the injured wife that the court dismissed the noble Lord's appeal Owing to the defect in the law which I have pointed out, Lady Campbell is practically without redress She has been injured in health, injured in reputation, publicly villified and privately slandered by a miserable wretch whom she is still compelled to call husband

Is not this anomalous and disgraceful in the extreme? Yet there are many cases continually occurring in all countries in which equal or greater misery is inflicted upon the innocent victims of man's selfishness, ignorance, or brutality It is high time that the protective ægis of the law should be extended over this numerous and long-suffering class All that is necessary is the enactment of a clause substantially stating that syphilis shall be sufficient cause for an action for absolute divorce, or for divorce with alimony, at the option of the aggrieved party It might also be advisable to add an amendment declaring the wilful concealment of syphilis or other venereal diseases at the time of marriage, or communication of their contagion at any time, to be a misdemeanor punishable by fine and imprisonment

I am aware that these proposals will not now meet with universal approbation, but I am convinced that they will meet with increasing favor in the future, and that it will not be many years before similar or even more stringent and more salutary measures will be incorporated in the statute books The fear that some may entertain that public demoralization would be increased by proceedings based upon such an enlargement of the divorce laws would not be realized The proposed amendments would practically prove most beneficent by their preventive, rather than by their penal character

MEDICAL PROGRESS

CARBONATE OF LIME IN CANCER.—DR PETER HOOD, in an article on "The Administration of Carbonate of Lime as a means of arresting the Growth of Cancerous Tumors," says Nearly twenty years ago the *Lancet* published a communication from me on the value of carbonate of lime in the form of calcined oyster shells as a means of arresting the growth of cancerous tumors and I am anxious once more to call attention to the subject, and to urge upon those who possess the necessary facilities that

a more extended trial should be given to this agent than it appears yet to have received My own opportunities of employing it in suitable cases have not been large, but the results which I have witnessed have been sufficiently remarkable to justify me in seeking for them a more extended publicity In the paper referred to I related in detail the case of a lady nearly 80 years of age, who was the subject of schirrus of the breast, and in whom the growth sloughed away and left a healthy surface after a course of carbonate of lime, administered in accordance with a recipe which was current in her family She manufactured her carbonate of lime by baking oyster shells in an oven and then scraping off the calcined white lining of the concave shell The substance thus obtained was reduced to powder, and as much as would lie on a shilling was taken once or twice a day in a little warm water or tea It was said that perseverance for at least three months was necessary before any good result was to be expected I presume that the powder would be almost pure carbonate of lime, but it might possibly contain a small admixture of iodine The immediate cause of the publication of my paper was a conversation with Mr (now Sir) Spencer Wells, to whom I related the particulars of the case above mentioned, and of one or two others which had fallen under my notice, and who suggested that the beneficial action of the powder might be due to the lime it contained He told me that he had used lime largely in the treatment of uterine fibroids and other tumors, and that he was convinced that processes of atrophy and calcification resembling the spontaneous change or degeneration sometimes observed in them were often produced or promoted by its action He added that he believed the change commenced in the coats of the arteries by which the tumors were supplied with blood, and that these coats underwent first an atheromatous and subsequently a calcareous degeneration, in either case with a diminution of the calibre of the vessel and a lessened capacity for the conveyance of blood

After the appearance of my paper I was applied to by several persons, with an inquiry as to whether their cases were suitable for the employment of the remedy, but in most of these instances I subsequently found that it had been taken for only a few weeks, and then abandoned because no result was apparent I should not hope for manifest benefit in any instance under three months of persistent treatment A notable exception to the ordinary want of perseverance was furnished by the wife of a physician practising at Reading This lady was the subject of a well marked schirrus of the breast, which I had myself an opportunity of examining After a fair and persistent trial of the calcined shell powder for three months, her husband reported to me that "the tumor had ceased growing and that she suffered no pain" She continued to take the powder for several months longer, and for several years her husband paid me an annual visit, always giving the same account, "that his wife never suffered any inconvenience or pain from her disease, the progress of which had been stopped"

The ordinary history of true cancer is such a dismal record of failure, that I think even a few instances in which benefit has been derived from a harmless remedy should encourage the profession to make trial of it in all suitable cases It would probably be inexpedient, generally speaking, to disclose the nature of the medicine, and the public mind is by degrees becoming permeated by the knowledge that many important medical actions can only be gradually produced We have no difficulty in inducing patients to submit to prolonged courses of mercury in the treatment of syphilis, and there is no reason why they should not do the same in a malady which, if possible, is even more formidable Up to the present time the narratives of cures of cancer have been chiefly suggestive of errors of diagnosis, and no assurance of the value of any proposed remedy can be obtained until it has been used in a sufficient number of instances to exclude the possibility of such errors having been committed in the majority of them Although the experience of Sir Spencer Wells with fibroids points to the probability of a beneficial action upon soft and vascular growths, those which I should myself select for the purpose of further investigation would be typical examples of breast schirrus, adherent tumors of stony hardness, attended by retraction of the nipple and lancinating pain About the nature of such it would seldom be possible to entertain a doubt As an example of the uncertainty which may overhang the true characters of growths which do not present the symptoms above described, I may mention that I was once consulted by a lady living in the north of England, who had a swelling in her breast which had been pronounced to be cancer by her family medical attendant, and also by two consultants called in from the neighboring country town She was urged to submit to an operation, but, before consenting she came to London for further advice She paid separate visits to Sir James Paget, to the late Mr Skey, and to me I was the first whom she visited, and I gave an opinion that the tumor was a harmless one and might be let alone Her second visit was to Mr Skey, who said without hesitation that it was a cancer, and advised removal Her third visit was to Sir James Paget, who said that the growth was innocent It was let alone and the patient has had no further trouble from it for twenty years Again, I was lately consulted about the case of a well-known nobleman, who had a soft growth in the front of his chest over the upper part of the sternum, which quickly attained a considerable size, and was pronounced to be malignant by eminent authorities It disappeared entirely under a course of small doses of the perchloride of mercury

It is therefore not in cases which admit of any reasonable doubt of their nature that I would desire to urge a trial of the lime powder upon the profession There are hundreds of instances of unmistakable cancer in which an operation, if performed, may perhaps for a time diminish suffering or may prolong life, but in which it cannot afford any well grounded hope of restoration to health For all such I would say that the lime ought to be persistently and fairly

tried It can do no possible harm, it need not interfere with any remedies for the present relief of pain, its action can be referred to a perfectly intelligible and probable hypothesis, and it has been of unquestionable utility in a sufficient number of cases to warrant us in reposing some confidence in its use We have a great hospital devoted to cancer, and cancer wards in others also, and I think the time has come when this simple means should be fairly tested by the profession It is not long since we witnessed an extraordinary eagerness to try the Chian turpentine, which was so much extolled by Dr Clay, and in support of which the *primâ facie* case was nothing like so strong as that in favor of the remedy to which I desire once more to call attention —*Lancet*, May 7, 1887

The Contagium of Scarlet Fever —The remarkable chain of evidence whereby Dr Klein has been enabled to substantiate the results of Mr Power's investigation upon the transmission of scarlet fever direct to man from the cow, seems to leave little room for scepticism, that in the streptococcus met with by Dr Klein, we have the effective agent in the etiology of this disease, and, scanty as prior observations are, imperfect as many of them have been, it is noteworthy that hitherto the scarlatinal microbe has been described as a micrococcus Coze and Feltz found micrococci in scarlatinal blood, Cornil in the urine in scarlatinal nephritis, Babes describes streptococci in post scarlatinal inflammatory products, and Pohl Pincus found "very minute micrococci adhering to the scales of the desquamating epidermis in scarlatina" (von Klein "Micro organisms," third edition) The isolation, cultivation, and successful inoculations practised by Klein, however, far outweigh all such partial observations But, as in the case of diphtheria, so here, it would seem that other observers have arrived at the conclusion that the scarlatinal microbe is a bacillus, and not a micrococcus Drs Jamieson and Edington, of Edinburgh University have completed a series of observations, which arrive at this result their plan of procedure being to examine the blood of scarlet fever patients as early as possible, to sterilize an area of skin and protect it from contamination till desquamation occurs, and then to examine the desquamated epithelia for organisms They found a bacillus in each of these media, and succeeded in reproducing a disease like scarlet fever in calves and other animals inoculated with pure cultivations of this bacillus Further tests by examination of the blood of the inoculated animals and pure cultivations therefrom also yielded positive results Until the details of their research are published it would not be fitting to attempt any critical comparison between them and those obtained by Dr Klein The fact that the blood of scarlatinal patients has been frequently examined without result makes it at first sight more probable that the minuter organism has been overlooked, but much also depends upon the technical skill of the observer, and bacteriological methods are daily being perfected It is curious that a disease so obviously contagious as scarlet fever should hitherto have baffled the attempts made to isolate its virus, and almost simultaneously investigations should be in progress with this object, and with such apparently conflicting results —*Lancet*, June 11, 1887

Suction-Pump Action of the Mammalian Heart —That the heart acts not only as a force-pump during its systole, but during its diastole actively expands and thus gives rise to a negative pressure, which causes blood to move from the systemic veins to the right auricle, has long been maintained But the question still remains whether, after the thoracic cavity has been opened, the heart expands in diastole passively in consequence of the positive pressure exerted by blood drivers into its veins, or actively, and in the latter case, by causing a negative pressure, causes blood to flow towards itself, even when there is no positive pressure in the venæ cavæ

The outcome of the experiments of Drs H Newell Martin and Frank Donaldson is this that once the "aspiration of the thorax" has been eliminated, the right auricle of the mammalian heart will not receive blood unless supplied to it under a decided, if small, positive pressure While the heart in the closed thoracic cavity may, and probably does, act as a suction pump, this is not due directly to an active expanding force of the heart, but is the secondary result of the pneumatic conditions prevailing within the normal closed chest cavity Any cause diminishing thoracic aspiration must, therefore, greatly hinder the work of the heart, and it is probably more in this manner that the circulation is impeded in certain cases of hydro or pneumothorax than by direct pressure exerted on the heart itself —*Studies from Biolog Lab Johns Hopkins University*, Vol IV, No 1

Hypodermic Injections of Cocaine in Tetanus —Dr M Lopez reports the following case in *El Genio Medico Quirurgico*, for February 7, 1887 M G , 50, laborer, after working in the wet and cold complained of rheumatic pains of back and limbs Three days later he had marked opisthotonus and painful cramps, and all the symptoms of idiopathic tetanus Chlorol hydrate and morphine were prescribed For three days the patient was kept under the influence of these drugs, with the result that the pain was lessened, but the muscular rigidity and cramps increased He now became unable to swallow, and death seemed imminent Morphine was injected hypodermically, but was followed by no amelioration of the symptoms Three syringefuls of the mixed solutions of morphine and cocaine (each 5 per cent) were then injected The effect was immediate After two hours, he could move the limbs, turn in bed, and open his mouth On the next day he was going on well, slight trismus and stiffness of the neck remained On both sides of the neck, and *at the angle of the jaw*, a fourth part of the syringeful of the same solution was injected On the next day all the symptoms had disappeared The patient rapidly regained strength —*London Medical Record*, May 16, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

THE MANAGEMENT OF EMPYEMA

A short time ago a very interesting discussion on this subject was had at a meeting of the Academy of Medicine of New York Were there nothing else to show the importance of the subject, the fact that it was made a special subject of discussion in the Section of Theory and Practice of Medicine of the Academy is sufficient And it may be said that almost the last days of his promising life were spent by the lamented E Darwin Hudson in the preparation of the work for that evening, in order to secure a representative discussion

One of the most important papers read was by DR L EMMETT HOLT, on "Spontaneous Absorption in Empyema in Children, and the relative Advantage in Children of Aspiration and Early Incision " While spontaneous absorption may possibly occur it is very rare, and it is evident that the chances of recovery by Nature's unaided efforts are very small The indication, then, is to get rid of the pus in the easiest and safest manner, and the best methods for doing this are aspiration and free incision The following advantages are claimed for the former 1 Simplicity, 2 Freedom from danger, 3 That it does not remove the fluid rapidly, 4 That it does not require general anæsthenia, 5 That it does not require the confinement of the patient to bed, 6 That many cases are cured by aspiration alone The disadvantages of the method are 1 The entire quantity of fluid cannot be removed by this means, 2 When septa exist in the pleural cavity but one division of the latter may be evacuated, 3 The terror often excited in children, especially when the aspiration has to be repeated, is a serious obstacle to its success, 4 There are certain cases in which aspiration is not available, and if the case is allowed to go on for a considerable time without evacuation, septicemia and other serious consequences may result

Among the advantages of incision are, its universal applicability, the fact that it enables the surgeon to explore the pleural cavity thoroughly As to the use of general anæsthetics, Dr Holt thought they should not be resorted to, as he knows of two cases (although both in adults) in which death resulted from rupture of a bronchus Local anæsthesia is, therefore to be preferred on the ground of safety While the exposure of the cavity and the admission of air were formerly well-founded objections to incision, since the introduction of antiseptics this is no longer the case Of 63 cases collected in which the operation was done under strict antiseptic precautions there were but two deaths, and, contrasting this happy result with former statistics, he thinks that no more complete evidence could be furnished as to the advantages of anæsthetics As to duration, out of 80 cases in which antiseptics are used, 5 cases lasted four months or more, and in the remaining 75, the average duration was six weeks In 21 it was one month or less In cases in which antiseptics were not employed the average duration was six months

Dr Holt's conclusions are somewhat as follows 1 All methods yield better results than non-interference 2 No one should ever be left to the unaided efforts of nature 3 Aspiration holds out a possible chance of cure, especially if the empyema is localized 4 If, after two aspirations, the fluid continues to accumulate, this method should not be persisted in 5 In large effusions it is well to make an aspiration before resorting to incision 6 In all other cases a free incision should be made, preferably under local anæsthesia Early incision, perfect drainage, and complete antisepsis, in the words of Wagner, offer the best chance of success in dealing with empyema

---

DR HUBER, in a paper on "Acute Empyema in Children," advocated the use of the hypodermatic syringe for diagnostic purposes, and expressed the opinion that the more promptly surgical interference was made, in general, the better the results would be, provided this be not done during the first few days of the attack As a rule, it is better to wait until a week or ten days have passed, so as to allow the acute febrile symptoms to subside, and give the patient a chance to rally Dr Huber agrees that aspiration should first be resorted to, but if the result is not satisfactory, incision should not be long de-

layed, as the disease is characterized by fibrinous deposits as well as by purulent effusion, and the fibrin may decompose and cause sepsis Local anæsthesia is secured by cocaine, and in order to prevent the drainage tube from slipping into the cavity he uses Baxter's method Injections of bichloride solution (1–5,000) are used in all his cases The retraction of the chest remaining on the affected side may be overcome by suitable gymnastics and exercise in the open air

---

In a general consideration of the *surgical treatment of empyema*, DR ROBERT ABBE considered aspiration of more service in children than in adults, and as it is somewhat repugnant to the surgical mind to leave even a small quantity of pus in a place like the pleural cavity, he thinks complete evacuation should be practised as soon as it is evident that aspiration is insufficient to effect a cure The best results thus far have been obtained from free incision In doing this he uses a carbolic spray produced by a simple hand-bulb Two large drainage tubes, of the thickness of the little finger, are advisable, and he usually dresses the wound with bichloride gauze and iodoform A thorough outlet is essential, and the other important factor in the success of the treatment is the purity of the wound In the great majority of cases he does not think it necessary to inject the cavity, but when there is a hectic condition antiseptic injections, followed by hot-water ones, should be employed Two serious results have been observed from injections, namely toxic symptoms from the agents used, and sudden death, due probably either to thrombosis or reflex influence The drainage tube occasionally causes denudation of the periosteum of a rib, which has been erroneously designated as necrosis When this occurs resection must be done, but he thinks it unjustifiable to resect at first When there is decomposing fibrin, resection is sometimes called for in order to secure free irrigation, and occasionally when a suppurating cavity remains after empyema, Estlander's operation of resecting several ribs is very satisfactory As regards anæsthesia for incision, he thinks that in children a few whiffs of chloroform answer perfectly well, but in adults local anæsthesia with cocaine is preferable

---

DR ALFRED L LOOMIS believes that acute empyema is very common in children, and when he finds that a child's chest fills rapidly he feels pretty confident that empyema is present The treatment which he adopts is, in the main, such as has already been described Acute empyema in adults is a totally different affection, being an infectious and dangerous disease, often proving rapidly fatal, and it cannot be cut short by removing the products of inflammation After the acute stage has passed, however, he thinks incision does good, and is called for Chronic empyema is not a simple pleurisy We have not merely the pleural cavity to deal with, but a serious constitutional condition, and it is necessary to sustain the patient's vital forces in every possible way

---

DR JOSEPH E WINTERS differed materially from Dr Loomis and some of the other speakers in his views of empyema in children He has careful records of 90 cases of pleurisy in children, and in only 4 of these was there empyema In the latter this condition already existed when the patients first came under observation, and of the remaining 86 cases, not a single one terminated in purulent effusion In simple pleurisy the temperature sometimes rose to 103° and 104°, but under rest, hot applications, and sedatives, the cases almost all terminated in resolution in the course of a week or so, and in no case under his care has empyema resulted Two cases were operated on account of the mechanical pressure produced by the large effusion present, and while they were both fatal, at the autopsy no pus was found in either case He has never seen a case of empyema in a child in which there was not an abundance of serum, and he therefore thinks that the fluid in such cases is capable of absorption Hence the condition is very different from that existing in empyema in adults, and he does not deem it necessary to resort to surgical interference except to relieve the effects of mechanical pressure on the viscera He also objects seriously to the use of the hypodermatic syringe or the aspirator, unless there is surgical necessity, as he thinks the entrance of the needle into the pleural cavity is a very common means of turning a simple effusion into empyema, an opinion in which Dr Francis Delafield coincides When in cases of empyema operative procedure is called for, he thinks that free incision was greatly preferable to aspiration

---

Cases have been known in which hæmorrhage after incision for empyema was sufficient to cause death DR T HERRING BURCHARD mentioned two such cases, both most probably cases of capillary hæmorrhage, such as is sometimes seen after sudden and complete evacuation of a distended bladder As suggested by DR HEINEMAN, this may be prevented by injecting a certain amount of fluid into the pleural cavity, and allowing it to remain In the same way may the coughing set up by the removal of fluid from the pleural cavity be relieved

MEDICAL COLLEGES IN GOOD STANDING

The first part of the first *Section* of the Act to Regulate the Practice of Medicine in the State of Illinois reads as follows

"That no person shall practice medicine in any of its departments in this State unless such person possesses the qualifications required by this Act If a graduate in medicine, he shall present his diploma to the State Board of Health for verification as to its genuineness If the diploma is found genuine, and from a legally chartered medical institution *in good standing*, and if the person named therein be the person claiming and presenting the same, the State Board of Health shall issue its certificate to that effect signed by all the members thereof, and such certificate shall be conclusive evidence as to the right of the lawful holder of the same to practice medicine in this State"

At the regular quarterly meeting of the Illinois State Board of Health held in the Grand Pacific Hotel, Chicago, July 8, 1887, the following resolution was adopted

"*Resolved*, That the phrase 'medical colleges (institutions) in good standing,' in the first Section of the Act to regulate the practice of medicine, approved June 16, 1887, is hereby defined to include only those colleges which shall, after the sessions of 1890–91, require four years of professional study, including any time spent with a preceptor, and three regular courses of lectures as conditions of graduation"

The questions, what is the legitimate meaning of the phrase "a legally chartered medical institution in good standing," and what the evidence required to establish its "good standing"? are assuming an importance that will, at no distant day, compel answers from some tribunal whose decisions will command respectful obedience Does the *good standing* of a medical institution depend upon the fact that it faithfully and honorably complies with the requirements of its charter and the promises of its annual announcements to the public, and that its graduates are cordially received and recognized by the medical profession and the community? Was that the sense in which the Legislature of Illinois used the words "good standing" in the law for regulating the practice of medicine, or were these two apparently innocent words intended to confer upon the Illinois State Board of Health full *legislative power* to dictate alterations and amendments in the powers, duties and curriculums of all the medical colleges in the United States, in order to place them in the attitude of "good standing" before that Board? And not only this, but also the extraordinary power of legislating in advance and defining what the medical educational institutions must do three years hence as set forth in the resolution quoted above The resolution declares "that the phrase 'medical colleges in good standing,' is hereby defined to include only those colleges which shall, after the sessions of 1890–91, require four years of professional study, and three regular courses of lectures as conditions of graduation" Having *hereby* and *now*, declared that *only* those medical colleges which comply with certain specified conditions in 1890–91, shall be recognized as in good standing, will the Board go on recognizing the diplomas of colleges *not in good standing* for the next three years, or is the concentrated wisdom of homœopathy, eclecticism and regular medicine, as combined in the Illinois State Board of Health, equal to the task of discerning now which of the colleges will comply with the conditions specified after 1890 Finally, is the Illinois State Board of Health an executive body charged with certain clerical and important duties, or is it also a legislative body with full power to enact all such laws as it may deem necessary to regulate the education and practice of the medical profession of the State, altering and amending, elevating or debasing the same, from year to year according to its own pleasure? Let no one infer that the foregoing questions have been prompted by any opposition to a period of four years of medical study and three annual college courses of lectures, of not less than six months each, when the same shall be embodied in a carefully prepared law containing such additional provisions as are necessary for its efficient execution, and enacted by the acknowledged legislative authority of the State But we are getting a little weary in witnessing more quack *medical legis*tion than we have quack medical practice

INTERNATIONAL MEDICAL CONGRESS RAIL ROAD RATES

The rate upon all railroads, for those designing to attend the Congress to be held at Washington in September next, has been made at one and one-third fare for the round trip, tickets to be issued on the certificate plan We ascertain from the passenger department of the Baltimore & Ohio R. R Co, that no pains will be spared by this Company to afford all the comforts in their power to promote and enhance the pleasure of visitors to the Congress, and that the railroad rate from Chicago to Washington and return will be $23 35

The above announcement of the general reduc-

tion of railroad rates for all those intending to attend the International Medical Congress, to convene on the 5th of September next in Washington, D C, indicates that the preliminary arrangements are nearing completion Several months since liberal rates of reduction were announced for nearly all the important transatlantic steamship lines, and many on the other side have already engaged their berths for the voyage The reduction of hotel rates in Washington, the engagement of suitable rooms for the Congress and its many Sections, were announced soon after At the recent meeting of the Executive Committee a speedy completion of the programme of scientific and practical work was provided for, and the Committee of Arrangements at Washington have planned a liberal and appropriate series of entertainments, embracing an excursion to Mt Vernon, a grand banquet, and a more grand excursion for the guests from other countries, from Washington to Niagara Falls and return to the sea board Only one thing more is necessary to relieve the hard working Committee of Arrangements at Washington from anxiety, and that is to have three or four more State Medical Societies in rich and populous States, like Ohio and Indiana, follow the example of Pennsylvania, Illinois, and Michigan, and send to the Treasurer of the Congress, $1000, $750, or $500 each, and as many of the Societies in the larger cities follow the example of St Louis and Pittsburgh, or Alleghany Co, by sending $200, or $250, each, and thus make the entertainment fund good But individuals who have plenty need not wait for societies to do all, but should send their contributions at once It is important that all money, either from societies or by individuals should be forwarded as early as possible to the Treasurer, Dr E S F Arnold, Newport, Rhode Island

ADDRESSES FOR THE NEXT ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION

We learn from the Chairman of the special Committee, that Professor J L Cabell, of Va, who was selected to deliver the Address on State Medicine at the meeting of the Association to be held in Cincinnati, May, 1888, has been constrained to decline on account of poor health, which will be very generally regretted The Committee have, however, been very fortunate in securing the services of H P Walcott, M D, of Mass, in the place of Professor Cabell Dr Walcott has been long and efficiently connected with health matters in Massachusetts and is an Ex-President of the American Public Health Association, and an address by him will be listened to with more than ordinary interest Dr E M Moore, of Rochester, N Y, has accepted the appointment to deliver the Address on Surgery at the meeting to be held in Cincinnati Dr R Beverly Cole, of California, who was selected to give the Address on General Medicine, has not yet made any reply to the invitation extended by the Committee

THE ILLINOIS LAW AND INDIAN DOCTORS.—The amended Practice Act which enables the State Board of Health to deal with itinerant "doctors," "Indian doctors," and the like, seems to be driving some of them from this State The newspapers this week show that a good many of them are in serious trouble in adjoining States

CHOLERA IN SICILY.—A cablegram of July 12, says that cholera, which is broken out in Sicily, is increasing There have been 200 cases at Catania, with 140 deaths The Neapolitans are alarmed on account of the arrival in their city of numbers of fugitives from Sicily

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, May 2, 1887

THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

(*Concluded from page 59*)

URETHRAL AND VESICAL CALCULUS

This is a urinary calculus removed from the urethra, and with this history The man says he has had trouble for six years in urination, that he has been treated a good many times for retention of urine, that he suffered great pain and distress in urination during that time Three weeks ago he was brought to my house for the purpose of relieving him of acute retention, he had not passed urine for six or eight hours, and was in great distress Supposing I had a case of tight stricture to deal with, I attempted to pass a very fine whalebone bougie I passed it down the urethra and found that it struck against and was stopped by something that seemed rough I then attempted to pass in a metallic sound, trying different sizes, but found it impossible to strike this body with any sound, the only instrument I could get in contact with it was a whalebone bougie Then I introduced my finger into the perineum and immediately it came upon the foreign body bulging directly into the perineum before the finger entered fairly into the anus, apparently lying in a horizontal posi-

tion, and so evidently in the membranous portion of the urethra I advised immediate operation, as I could not get any instrument into contact with the foreign body It was a new idea with the patient that he had a foreign body in this place, and he wanted to consult with his wife, he went away and two weeks subsequently he came to me for operation Upon examining the patient this body was now found just below the pubes I again made attempts to come into contact with the body through the urethra, supposing I might be able to withdraw it from the urethra with the forceps, but by no effort could I bring any of my instruments in contact with it During the first examination I made efforts by means of my finger and thumb to force this body back into the bladder, but failed to do it, before advising operation After placing him under an anæsthetic I made a direct incision and exposed the stone, which I had no difficulty in turning out It is very hard and shaped so as to most easily follow along in the course of the urethra The urethra in front of it was contracted down to an extreme degree The man is well For four days he passed water through the wound in the perineum, but in less than a week he passed it through the urethra.

In another case I was summoned to see a man whom I found suffering great agony in the desire to pass water The history was that he was taken with this trouble in the woods in Alabama, where he was hunting for timber, and he came to Chicago to be relieved of his trouble Upon examination I found *half way down the penal portion of the urethra a foreign body* I attempted to withdraw it with the forceps, but the loss of blood was severe, so I adopted this plan without an anæsthetic, and without any assistance, I displaced the elastic integument of the viscus to one side and fixed the foreign body, and then made an incision directly on to the stone and let it out The opening in the urethra was covered by the opening in the skin, and the man had no trouble except a slight amount of pain for a few days The stone was about the size of the end of the finger, and was very irregular

Three or four years ago Dr Moore sent to me a man about sixteen years of age, with a note saying this young man had a needle in his bladder The young man denied it, and said he had only a great deal of trouble in passing water When the sound got into the membranous portion of the urethra it struck the foreign body I made a good many attempts to remove it by means of forceps, I could seize the body with small forceps and withdraw it a short distance, but failed to get it any further I followed the young man to his home and calling on Dr Moore to administer an anæsthetic, I removed it without any difficulty by direct incision I will say that in examining the case the needle could be felt projecting into the bladder, and probably the anterior portion of it into the membranous portion of the urethra It is a large sized darning needle, as can be seen The patient never passed any water through the opening of the wound, the urine was extruded from the urethra the very first day

The vesical calculi which I have to show you embrace two stones that were removed from the bladder of a young man 18 or 20 years of age You can see that they fit together, and have rubbed each other smooth The young man had something of this history I saw him when he was 14 or 15 years of age, three years before he had received an injury by a fall from a building, when he struck upon the perineum and produced a traumatic rupture of the urethra, which finally recovered, and was followed by a cicatricial stricture, for which he submitted to an operation to by Dr Bogue, at that time Some five or six years after that he came under my charge with a return of the traumatic stricture They are difficult to overcome and are apt to return It was so tight that the smallest instrument could not be passed through it, so perineal section was determined upon Up to this time no examination had been made of the bladder, after the division of the stricture in the perineum and the entrance into the membranous portion was made, followed by the introduction of a small probe into the bladder, these stones were found and these two large calculi were removed from the median incision The incision was not increased laterally in any way, they had become partly prostatic in character and had dilated this portion of the urethra to such an extent that the median incision was all that was necessary

I show another case of calculi which is important When I exposed it in the bladder it was in the condition you see it now, and it raises the question whether a stone is ever fractured in the bladder This was taken from a man 67 years of age, by the lateral operation It was found fractured into these two pieces The man did not have any difficulty in his recovery, notwithstanding his age He passed water through the perineum for only three days Here is another stone If you look at one surface you will see that it is covered with blood When I made the examination it was impossible for me to find this stone except by passing the sound in one certain direction, and it immediately made the impression on my mind that the stone was fixed in its position I did a lateral operation and upon entering the bladder I found that only the upper part of the stone was exposed, the lower half was imbedded in the mucous membrane of the bladder By a considerable effort with one blade of the forceps I finally detached it from its bed This man was 24 or 25 years of age His wound was healed in nine days, and he was out on horse-back the second week after the operation It may be interesting to show you a specimen which illustrates the fact that the bladder may contain a stone of considerable size and for a long time without any symptoms whatever This was obtained under the following circumstances During my study of topographical anatomy, where I made a good many sections of the frozen bladder, I selected one patient who was not emaciated, where the whole surface shows evidence of good health He died of pneumonia I had his body frozen and made sections for other purposes In making a longitudinal section through the perineum I found a stone in his bladder It was of considerable size, as you see, but no symptoms in this patient indicated

the possible presence of a stone in the bladder It is as large as a turkey's egg, and is now in exactly the position occupied when the section was made

DR EPHRAIM INGALS once had a case calculus in the urethra that may be of interest in its relation to this subject, as presented by Dr Parkes A healthy man of about 25 years came to me, being unable to void his urine On examining him I found the bladder distended nearly to the umbilicus, and he was in great pain On attempting to introduce a catheter the instrument was arrested about one inch before it reached the membranous portion of the urethra As I do not practice surgery, I sought at once to place my patient in charge of one who made this branch a specialty I went with him to the office of Dr Moses Gunn, who introduced a metallic catheter of medium size by the stone into the bladder, and the water was all drawn off Considerable force was necessary to carry the instrument by the stone, and some blood followed the operation This was near evening The next morning I visited my patient, hoping to be able to remove the stone with forceps, but found that during the night the stone had been expelled It was about one half an inch long by one fourth of an inch in diameter, of irregular contour, and rough on the surface In three days the patient died from pyæmia No post-mortem examination was made, but I presumed that the urethra was wounded at the point where the catheter passed the stone The practical question this suggests is would it not have been better to have removed the stone by cutting down upon it, as was the practice of Dr Parkes in the case he has reported?

DR HENRY J REYNOLDS exhibited a stone passed involuntarily from the bladder of a woman, or rather without surgical interference, through the urethra It was an extremely large stone to pass through even the female urethra, and would of course have been an impossibility in the male The history in brief is as follows In July, 1885, I was called to see the lady, aged 16, small and delicate She had been troubled with frequent urination for two years, which ultimately became so bad that she was obliged to quit work The symptoms gradually became more and more aggravated until two months afterwards, when they finally culminated in the passage of this stone, with much straining and pain It is 1⅞ inches long, 1¼ inches broad, and weighs 405 grs There was no vesico-vaginal opening or fistula, but the meatus was very much lacerated and would admit the index finger readily into the bladder two weeks after the passage of the stone The bladder was examined for other calculi but none were found The urine dribbled away involuntarily for several months, finally the patient became able to retain part of it, and she is now able to retain all the urine and has become quite healthy This report may be verified by Dr E L McAuliffe, of Chicago, who also examined the case

DR PARKES said, in answer to Dr Ingals' question, that he would certainly make a direct incision in every case in which there was any difficulty in removing the stone from the urethra

DR WM T BELFIELD reported a case of

TRANSPLANTATION OF AN UNDESCENDED TESTICLE

The patient was a healthy youth 20 years of age, in his thirteenth year a small lump appeared in the right groin, during several years thereafter it increased in size, and frequently occasioned severe pain, especially during active movement Two physicians, consulted during this period, pronounced the swelling a hernia, and advised trusses, but these failed to relieve the symptoms, the patient being frequently unable to work or walk for several hours

The tumor was found, on examination, to be a fairly developed testicle, lying upon the middle of Poupart's ligament, just exterior to the external inguinal ring, no hernia The right side of scrotum was undeveloped The coverings of the testicle were exposed, the organ and its cord loosened by dissection, and the testicle was pushed down into the scrotum and stitched to the bottom thereof Dressings were so applied as to prevent retraction by the short cord The stitches, however, pulled out After healing the testicle was found, freely movable in its tunic, at the upper portion of the scrotum, just below the pubic arch The patient attends to his duties with perfect freedom from pain and discomfort This appears to have been one of those unusual cases in which a testicle, retained in the inguinal canal until puberty, resumes at that period interrupted descent Such tumors may easily be mistaken—as was this one—for hernia

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, April 7, 1887

THE PRESIDENT, THOMAS M DRYSDALE, M D, IN THE CHAIR

(*Concluded from page 652, Vol VIII*)

DR W H PARRISH reported a case of

LARGE OVARIAN CYST CURED BY EVACUATION, DRAINAGE AND OBLITERATION OF ITS CAVITY

On January 27, 1887, I operated on a Jewess, 27 years of age, for the removal of a large abdominal cyst I saw patient the first time on Jan 24 She was then under care of Dr N Hickman, who placed her under my care for operation She was the mother of four children, the youngest only four months of age In her last labor she had been attended by a midwife and but little reliable information could be obtained with reference to the existence of an abdominal tumor during the three weeks following labor The patient stated however, that her abdomen was not unusually large after the birth of the child About three weeks after labor she was under the care of Dr Hickman for a few days, during which time she presented the usual symptoms of general peritonitis She then passed into the hands of others and was not seen again by Dr Hickman until just before I operated During this period of three months she was visited by a number of medical gentlemen Aspiration was resorted to by one of the number Laparotomy was repeatedly urged but persistently refused by the pa-

tient The abdomen increased rapidly in size Pain became constant, appetite entirely disappeared, vomiting occurred at very short intervals Hectic became marked with occasional rigors, and emaciation had reached an extreme point The lower extremities were but slightly edematous and there was no special enlargement of the superficial abdominal veins The abdomen was greatly distended, tense and tender, and the patient was so exhausted that she could not rise from the semi recumbent position She was at once transferred from her surroundings of filth and poverty to a private hospital, and I operated without delay as it was apparent that without surgical relief her life could last but a few days longer There were present Drs Hickman, R P Harris, S D Lazarus, John Hand and F A Packard The patient had a general sponge bath with soap and water and stimulants had been administered Before etherization the pulse was 130 per minute There was a dull percussion note over the entire abdomen anteriorly and the diaphragm was pushed well upwards by the tumor Fluctuation was distinct though palpation suggested a thick walled cyst rendered very tense by reason of the degree of distension I gave a diagnosis of ovarian tumor with suppurating contents and extensive adhesions Incision 2½ inches long in median line, without opening the peritoneal cavity the knife cut into the cyst wall which was easily recognized by its consistence, color and anatomical elements There were anterior adhesions of great extent and firmness The cyst was opened and a quantity of pus like fluid of offensive odor escaped The cyst did not empty itself and the introduction of two fingers showed large masses of lymph like character varying in density and size The introduction of the hand was required to remove these masses In the interior were a number of thin septa such as are seen in colloid ovarian tumors The great bulk of the contents was an apparent mixture of pus, lymph and detritus, while part of the contents presented the translucent appearance of the fluid of some ovarian tumors After thoroughly emptying the tumor it was evident that its walls were everywhere adherent No portion of the wall could be brought into the abdominal incision There were evidently dense adhesions to the liver, spleen, stomach, intestines and to the pelvic brim and contents The tumor did not dip down into the pelvis, the walls were everywhere thick and strong, At this stage of the operation the patient's condition seemed threatening imminent death, pulse 140 and exceedingly feeble The ether was withdrawn and was not used again, stimulants were given hypodermically The thickness of the cyst walls and the universal adhesions rendered the case one well adapted to treatment by drainage I decided not to remove the cyst I now thoroughly cleaned its interior, introduced a glass drainage tube and approximated around it the walls of the abdomen and cyst, carrying the sutures into the cyst wall but not through it

The patient rallied well, and there was no ether vomiting For several days the discharge through the tube was of a purulent fluid similar to portions of that removed during the operation, its character then changed to that of ordinary pus The cavity of the cyst was daily emptied of about two ounce of fluid, and phenol sodique injected in the same quantity The abdomen was covered with a compress and binder to keep the inner cyst walls approximated, and to encourage absorption of the exuded lymph The area of dulness diminished rapidly from day to day and the discharge diminished with surprising rapidity At the end of two weeks a shorter drainage tube was substituted and at the end of three weeks rubber tubing about three inches in length was introduced in lieu of the glass tube The wound was entirely healed by the end of the fourth week Examination showed a small, flattened mass, two by one inches, underlying the abdominal wall and adherent to it The patient's appetite became ravenous a few days after the operation, and she was fed liberally The recovery of the patient is now complete, and I feel confident the cyst cavity is so effectually obliterated that it cannot refill Does the rapidity of the shrinkage and disappearance of the cyst indicate that it wat not an ovarian tumor? I answer in the negative It was not an extra nor an intra peritoneal abscess, for abscesses do not contain such septa nor such fluid The character of the contents and septa distinguish this case from two cases operated on by Tait, in which he ascribed the tumors to distension and suppuration of sacculated urachus In making the incision I recognized the peritoneum external to the cyst In my own mind there is no doubt as to the ovarian origin of the tumor A specimen of the tumor was examined microscopically by Dr F A Packard who has written as follows "I found it to be composed of numerous fatty degenerated epithelial cells, leucocytes and granular material entangled in a dense meshwork of fine homogenous fibrin like fibres There appeared to be no definite arrangement or other evidence of an organized tissue The general appearance was that of a tissue that had undergone complete fatty degeneration I, unfortunately, ruptured the small cyst, before I could collect the contents for examination" The paper will be published in full in the *American Journal of Obstetrics*

Dr R P Harris remarked that the cyst contents chiefly of a thin greenish fluid of a puriform character in which were found masses of cell structure, some of them as large as a fist, on the surface of which were in some instances still to be seen, small translucent cysts containing a yellowish fluid, there was also noticed during the emptying process an escape of fluid from cells which had preserved their integrity, and which resembled to the eye what is often seen in tapping during ovariotomy of multilocular tumors My own impression during the operation was that the tumor was ovarian The emaciated state of the woman, her rapid pulse, and the strong adhesions of the cyst wall to the abdominal parieties and viscera, satisfied me that any attempt to remove the cyst would cause the patient either to die upon the table, or of shock in a few hours Judging from the recoveries after the secondary operation in abdominal pregnancies where it has been found of vital importance not to remove the cyst, a measure the value of

appendix, and also near its extremity, and the sight of the ulceration and the intervening portion removed The operation was done with all antiseptic precautions and a drainage tube was inserted into the bottom of the abscess The temperature of the patient is nearly a degree lower (98 6°) this evening than it was this morning

Early in the illness a large quantity of urine was passed On Sunday, and again on yesterday, he passed a small quantity of blood in his urine Probably the abscess was pointing into the bladder The position of the tumor was unusual The protrusion was almost in the median line It is this that made us hesitate about adopting the diagnosis of perityphlitic abscess I learned to day that the patient had been subject to occasional attacks of cramps in the stomach for a year or two, but these were not referred especially to the right side

On making the section, pus was found in the muscles, and when the peritoneum was reached, it was found thickened, and pus was also under it As a result of the inflammatory process, the abscess had been shut off from the general peritoneal cavity The posterior layer of peritoneum had probably been destroyed by the abscess A solution of bichloride of mercury (1 2000) was used to douche the wound until the peritoneum was opened, when hot water was substituted The walls of the abscess cavity were scraped with the curette, and all sloughy tissues removed The wound was closed with deep and superficial catgut sutures, and iodoform applied upon the antiseptic gauze

DR EDWARD JACKSON reported a case of

SYMPATHETIC OPHTHALMITIS, WITH KERATITIS, RECOVERY, AFTER EXCISION OF THE EXCITING EYE

Sympathetic ophthalmia, like small-pox, is now more rare than formerly, because we have for it a reliable prophylactic That cases still occur is due to the fact that prophylaxis is sometimes neglected, and the continued diminution of their number depends, as with small-pox, upon keeping alive a just appreciation of the serious character of the disease, and the necessity for prophylactic measures

George M , æt 39, a carpenter came to me for inflammation of the left eye, which had commenced two weeks earlier, the eye having before that been perfectly well It presented a moderate conjunctivitis, the cornea was slightly hazy throughout, and there was a superficial ulcer near its lower margin and another near the upper outer border There was a marked pericorneal zone, broadest opposite the ulcers The iris seemed normal, the pupil was 5 mm in diameter, circular and immovable (he had been using atropia), and subsequent trials showed that 5 mm was the widest dilatation of his pupil that atropia or similar mydriatics would produce The media back of the cornea were normal The optic disk was *very decidedly* reddened, but not swollen nor indistinct of outline, the fundus otherwise normal The patient and Dr Hoskins agreed that the eye looked decidedly better than it had a few days before The right eye presented an adherent leucoma near the outer margin of the cornea, which was otherwise clear The pupil was distorted and closed by a dense white membrane, which, toward the inner side, fell back a little from the margin of the iris, indicating that the lens was absent from its normal position The tension of the globe was below the normal Good central light perception, but with the field narrowed in all directions, especially upward Six years before, the eye had been struck by a fragment of steel flying from the edge of a cold chisel This was followed by severe inflammation, which subsided in a few weeks, and *the eye had never been at all sore since* It was now free from undue tenderness or other symptom of inflammation The treatment ordered was applications of 1 1 to 120 solution of silver nitrate to the palpebral conjunctiva, and continuance of the atropia, with dark glasses Two days later the eye became decidedly worse He was confined to a dark room, atropia solution 1 to 60 was instilled every two hours, a saline cathartic was given, and he was put on the use of mercuric chloride and potassium iodide At the end of a week there was general hyperæmia of the eyeball The mass of the cornea was clearer, but there was slight keratitis punctata and distinct vitreous opacities, vision $\frac{12}{CC}$, great pain and photophobia I enucleated the right eye, finding it free from evidences of recent inflammation, but presenting in the ciliary region, below, a mass of lymph *the size of a split pea, in which was imbedded* a splinter of steel 3 mm long, and weighing between 2 and 3 grains The socket healed normally At the close of the operation, and still five hours later, the left eye was decidedly paler than before the right was excised The only change in treatment was the application of a blister to the left temple and the use of a drop of a 4 per cent solution of cocaine with each instillation of the atropia solution Next day the eye was worse, but after that it improved, and the patient is now thirteen months after the enucleation, working at his trade

Was this ophthalmitis due to the injury of the other eye, which for six years had given no evidence of active disease? In this case their was neither history, symptoms, nor collateral evidence to indicate syphilis or rheumatism It presented hyperæmia of the disk, serous iritis, keratitis punctata, vitreous opacities, plastic iritis, and repeated relapses What other symptom save the one under discussion could have helped to make the diagnosis more certain? Among the 211 cases collated in the report on sympathetic ophthalmitis made by its committee to the Ophthalmological Society of the United Kingdom in March of last year, twenty-three cases of this kind are included In four cases the intervals were eighteen, fourteen, ten, and eight years The committee say "Though the series is small, we may safely conclude from it that sympathetic ophthalmitis occurring after a long interval, and without any fresh inflammation of the exciter, is by no means likely to be mild" It may be questioned if the corneal ulcer and conjunctivitis had any necessary connection with the sympathetic disease Yet in three of the

cases which form the basis of the report mentioned corneal ulcer was noted and in one conjunctivitis Dr D Webster has reported as sympathetic a case of catarrhal conjunctivitis which had occurred in the service of Dr C R Agnew, and states that Dr H D Noyes had presented a case of sympathetic conjunctivitis to the New York Ophthalmological Society

The above points bear upon the diagnosis of sympathetic ophthalmitis Of equal importance are certain questions of treatment Atropin, I think, saved this eye from the baneful effects of posterior synechiæ The use of tonics was symptomatic Mercury was given internally on the strength of tradition, improvement occurred under its use, the relapse, running into plastic iritis, happened some days after its administration had been suspended Its local use caused no notable irritation, and was followed by rapid healing of the corneal ulcer But the most important point in regard to treatment is the question of removal of the exciting eye Here removal was followed by recovery In other cases recovery has occurred without removal Or, again, as in a case reported some years ago, by Dr A D Hall, removal has been followed by very great permanent damage or complete loss Referring again to the report above quoted, we find that of its cases the exciter was removed early in 64, of which 8 were lost, and it was removed very late or not at all in 65 of which twenty six were lost From their investigations that committee draws the very moderate conclusion, "that whether early removal of the exciting eye be positively useful in staying the disease or no, it is certainly not injurious, as no less an authority than Mauthner has asserted that it is when the sympathetic disease is of the 'serous' form"

Dr G Betton Massey presented

A RHEOSTAT, FOR THE UTILIZATION OF INCANDESCENT LIGHTING CURRENTS IN MEDICAL PRACTICE

The new building of the Orthopædic Hospital having been recently furnished with an incandescent lighting plant for which wires were laid throughout the edifice he determined to make use of the same current in the treatment of patients in different parts of the house in place of that derived from ordinary galvanic batteries To do this, it was necessary to use the current as it was delivered to the lamps in full strength from the entire secondary battery, as the many wires necessary to the use of a cell selector were out of the question The electromotive force of this current is only sixty volts, which is about equal to the full strength of an ordinary gravity battery of sixty cells or of a Grenet battery of forty five cells He had, therefore, merely to choose a rheostat or resistance medium that would be efficient with the full strength of any good chemical battery The wire rheostat was rejected for the double reason that it was expensive, and did not admit of delicate gradations, and the water tube, because it would have to be long to be efficient, and with the rod pulled up would be awkward in use

The rheostat exhibited, consists merely of a broad line of pencil mark on roughened glass extending around the greater part of a circle [1] One end of this broken circle of pencil mark is connected with a terminal of the battery, and the circuit is completed by a circular switch which makes contact with the pencil mark by means of a small metallic wheel A greater or less length of plumbago is thus included in the circuit with ease, and this material thinly spread out being a poor conductor, a great range of resistances is obtained In connection with the rheostat a milliampèremeter must always be used, the hand being on the rheostat and the eye on the meter With this rheostat and a meter attached to a battery all cell selectors may be dispensed with, and the whole battery used simultaneously and evenly The instrument was made by Mr Flemming, and is mounted with the meter on a ward table for use at the bedside Connection with the mains is made by thrusting a plug attached to the table into receptacles in the base boards near each bed in the wards, and beneath the lamps in the private rooms

Dr Massey also exhibited a

CHEAP, PERMANENT GALVANIC BATTERY

Its chief advantages are the cheapness of the materials used, its freedom from local action and creeping salts, and the long intervals that it will run without being touched It consists of a zinc rod, such as is sold for use in the Leclanché cell, clasped by rubber bands to a carbon rod, and resting in a saturated solution of chloride of ammonium and bichromate of potassium in simple water The carbon rod is one of those used in the arc light lamps, and, like the zincs, is both plentiful and cheap, one carbon rod broken in half serving for two cells The containing jar is an ounce quinine bottle Before attaching the wires to the carbons by winding and twisting, as shown in one cell, or by the pin and hole arrangement, as shown in another, the tops of the carbons must be treated with boiling paraffine to prevent interstitial creeping The elements are kept about half an inch apart by blocks of soft rubber The permanence of the cell is greatly improved by greasing the inside of the necks of the bottles and covering each with a piece of thin rubber to prevent evaporation Sixty cells give a strong and reliable battery, and the electro motive force is estimated at fully a volt per cell The total cost of the materials is only twelve cents a cell

Cicatricial Indications of Scientific Attainments, Their Scientific Aspect—Heidelberg Hospital—Carcinoma of Head of Pancreas—Carcinoma of Face—Riedinger's Method of Resecting the Knee—Schoenborn—Removable Plaster Splint—Sarcoma of Base of Skull—Iodoform—Leube and Naunyn

I left Stuttgart perfectly satisfied with the principal object of my visit and arrived in the famous

[1] A straight pencil mark rheostat was shown by Dr Jacobi to the American Neurological Society in 1885

[2] By permission of Drs Fenger and Senn

University town of Heidelberg April 6 I reached Heidelberg at the wrong time, as Easter vacation had commenced and Prof Czerny had improved this opportunity for obtaining a much-needed rest by a trip to the French metropolis I was very anxious to meet Czerny, not only to become personally acquainted with him and to see him operate, but also for the purpose of discussing with him certain topics in intestinal surgery which have engaged my attention for some time, and upon which I knew he could impart more information than any other surgeon

A look at the straggling students that remained during vacation must satisfy even the most superficial observer that the four years prescribed for study are not spent exclusively in the lecture rooms, hospitals and laboratories, or burning the midnight oil in boarding houses, as, almost without exception, they present a florid, healthy appearance not at all suggestive of hard mental work Every student wears his mark of honor, from one to twenty four scars indicative of the number of times he has been marked by his opponent in the defense of a real or imaginary question of honor As a rule, the left side of the face is disfigured, but when this has been converted into a checker-board incapable of receiving further impressions, it seems it becomes necessary to attack the other side, in order to increase the surface for recording the number of times he had met his man These scars are a study in themselves In size they vary from a mere scratch to a complete division of a cheek You can see recent scars, with an exuberance of granulation tissue and a high degres of vascularization, and the linear depressed scars of old veterans upon the field of honor, which have left the face in all stages of contraction and distortion Many of the faces, as far as looks are concerned, to the sight of an ordinary individual are maimed for life, but among students a man appears to be appreciated by the number of scars he can show These passports prove for him at all times and at all places that he has been a student, and as such they possess an intrinsic value One of the assistants in the hospital had so many marks that for the sake of curiosity I made repeated attempts to count them, but had to abandon the task as insurmountable as the counting of the stars of the firmament

From a scientific standpoint these scars present also interesting objects of study It is evident that the duels are not fought in an aseptic atmosphere, or that the wards have not been rendered properly aseptic, as all scars that I have seen seem to prove, from their size and ugliness, that primary union is the exception and not the rule I have come to the conclusion that the recipient of a wound under such circumstances is not anxious to obtain union by a minimal cicatrix, as such a thing might become invisible and he would have nothing to show externally in after life that he belonged to one of the learned professions Calculate, if you can, the time that is required to become the possessor of two dozen of scars Let us imagine that the assistant with countless scars had fifty genuine scars—and I am quite certain that this number is rather below than above the real figure—if he devoted to the acquisition of each wound and the subsequent healing process only one week, he spent one year out of the four prescribed by law in acquiring a scientific face That such students never wear the blue ribbon is well known, and it is safe to assert that the same individual with so many marks spent at least another year behind his beer-mug The much marked men seldom come to the surface in after life During my travels on the Continent I have scrutinized carefully the faces of prominent surgeons, and while some of them can show one or two, seldom more, decent scars, most of them have preserved the integrity of their facial integument during their student days, and devoted their time to nobler things It is a disgrace to the German government that the foolish practice of duelling, although forbidden by law is still tolerated If no other measure for the total suppression of this relic of the barbarous age can be enforced, I would suggest that double barrelled shotguns loaded with a handful of buckshot be introduced as weapons, and I can safely predict that duelling in Germany will soon have only a historical interest

Dr Bessel Hagen, Privat docent fur Chirurgie, and during Czerny's absence his representative, very kindly showed me through the surgical wards and explained the most interesting cases The surgical department of the hospital comprises four separate buildings, supplied with all modern improvements, and having a capacity for 200 beds The operating amphitheatre is a model of its kind, and affords ample room for 200 students Antiseptic precautions are carried out with scrupulous care Solutions of corrosive sublimate are used for irrigation, gauze compresses and sublimated wood-wool for dressing wounds Dressings are not removed for twelve days or more unless positive indications for an earlier dressing arise That antiseptic surgery is thoroughly practised in this hospital becomes evident from an inspection of the temperature tables, which show no material rise in all the cases which had recently been operated upon, and among them were many serious operations

A case of primary carcinoma of the head of the pancreas had been subjected to abdominal section for diagnostic purposes, but when the true nature of the lesion became evident by direct palpation, the wound was closed, as the disease had extended to adjacent organs The most prominent symptom in this case was profuse salivation

Dr Steinthal, first assistant, performed a very creditable operation on a woman 60 years of age suffering from a carcinoma of the face, involving the parotid region and external ear During the dissection it became necessary to extirpate the entire parotid gland Most of the branches of the facial nerve were dissected out of the gland and left intact The whole of the external ear was removed A number of the submaxillary glands which were found slightly enlarged were also removed The immense defect was covered by two flaps, one from the scalp and another from the side of the neck At a point corresponding to the external meatus a perforation was made in the flap Dr Hetzel, another assistant, made an amputation of the thigh in a boy suffering

from tuberculosis of the knee joint, and where a previous arthrectomy had been followed by a return of the disease, which involved the articular ends of the bones and surrounding soft parts to such an extent that this alternative furnished the only possible means to meet an *indicatio vitalis* Antero posterior cutaneous flaps were made, the end of the bone covered with a periosteal flap, all visible vessels tied before removing the constrictor, and after all hæmorrhage had been arrested, the muscles were sutured separately with catgut and the cutaneous flaps with silk, with the exception of two openings for bone drains Gauze compress was placed next the wound, and a large wood wool cushion as a covering for the wound

From Heidelberg I hastened to Wurtzburg, where I was more fortunate in finding the men I wished to meet, Professors Schoenborn and Riedinger, both teachers of surgery in the University In the evening Prof Riedinger called at the hotel and invited me to meet him at his private hospital next morning, to witness an excision of the knee joint after his method

The patient was a boy about 6 years of age, suffering from tuberculosis of the knee joint Evidently the disease was in its earlier stages, as the joint was only moderately swollen and did not present that sense of semi fluctuation as is the case in advanced fungus inflammation of this joint, at the same time the articular surfaces were not displaced The operation was performed as follows The whole limb was thoroughly washed with warm water and soap and subsequently with a 1-1000 solution of sublimate Esmarch's constrictor was applied about the upper third of the thigh, and a *longitudinal* incision made over the centres of the patella, dividing the tissues with one stroke down to the bone, and passing through the lower portion of the quadriceps and the tendon of the patella At a corresponding point the patella was sawn through in the same direction so that the divided patella and the soft parts presented two symmetrical halves which when separated exposed the joint fully to inspection, both by sight and touch Without much difficulty the lateral halves were so widely separated that the lower end of the femur was brought fully into the wound and the articular end was removed with a saw, the line of section being below the epiphyseal cartilage The tibial end was treated in the same manner At least two osseous foci were exposed by the bone sections, and each was carefully scraped out with a sharp Volkmann's spoon This long anterior incision fully exposes the upper recesses of the synovial sac, and renders the extirpation of the entire capsule an easy matter After the extirpation of the capsule with curved scissors the whole surface was irrigated with a sublimate solution and carefully dried, and the parts restored to their normal relationship, and the two halves of the patella tacked together by applying two catgut sutures passed through the tendinous covering and periosteum, but not through the bone

The only provision for drainage was a rubber drain introduced into the upper angle of the wound As the limb is kept in nearly perpendicular position for at least 24 hours, the drain occupies the most dependent position of the wound, and answers all requirements The remainder of the wound is closed with silk sutures A copious gauze dressing, embracing nearly the entire limb, is applied, over which a thick layer of absorbent cotton and equable compression by bandaging limb from toes to groin A posterior hollow splint, with foot board, serves to immobilize the limb The constrictor is not removed until the whole dressing is applied The first dressing is not changed for a week, when the drain is usually found outside of the wound As the wound at this time is usually firmly united, the sutures are removed and the limb put in a plaster of Paris splint Anatomically this operation presents a number of advantages I have always observed after making the transverse incision, that on account of muscular traction of the extensors of the leg, there is not only a tendency for separation of the fragments of the patella, but a constant traction always results in the formation of a wide and often ugly cicatrix in the skin, conditions which are avoided by the anterior longitudinal incision When the articular ends of the bones are brought fully into such a wound by forcibly flexing the leg upon the thigh, the entire synovial sac is brought into full view and rendered accessible to removal with scissors The tissues divided in the direction of the axis of the limb, serve a most useful purpose in securing immobilization during the process of repair

As Professor Reidinger states, this method of operation should always be resorted to in making an exploratory examination of the knee-joint, as in case further operative measures appear superfluous, the parts can be replaced and kept in contact by simple measures, and after the reparative process is complete the joint is anatomically in the same perfect condition as before the operation Professor Riedinger is firmly convinced of the utility and advantages of this operation over the ordinary method and resorts to it in all cases where arthrectomy or excision is deemed necessary, and is perfectly satisfied with the results obtained in a large number of cases

Hofrath Professor Schoenborn, well and favorably known as professor of surgery in the University of Konigsberg, has only recently succeeded the late lamented Prof Herman Maas Prof Schoenborn is only 47 years of age, and has left a splendid position and one of the best arranged surgical clinics in Germany, for a larger but more difficult field of labor The Julius Hospital in Wurtzburg is an immense institution, with a large material for clinical instruction, but the surgical wards are miserable, and the Government is not disposed to make any changes for the better The operating room is small and badly supplied with light If I remind you that Wurzburg has 1100 medical students, it is not strange that the new professor of surgery is sadly conscious of the defects of his clinic At the time I visited Schoenborn I found him happy in the presence of Prof Naunyn, one of his former colleagues in Konigsberg, who had come with his wife to pay his friend a visit

I was shown all cases of interest in the surgical wards and for the benefit of visitors, a plaster-of Paris

splint was made, which has been used for such a long time in the Konigsberg klinik, in the treatment of fractures, and for immobilizing joints It is the well-known anterior or posterior splint made of fibres of hemp impregnated with plaster of Paris paste, and accurately moulded to the parts until the plaster has set It makes an excellent removable permanent splint, and certainly is much preferable to the most ingenious and costly ready-made splints Another specialty of Schoenborn's is the removable water glass splint, which is much more durable and lighter than circular plaster of Paris splints, and is used extensively in the treatment of spondylitis and in flamed joints

The same day he removed a sarcomatous tumor from the base of the skull, through the mouth, after first dividing the soft palate As a preliminary measure the trachea was opened and plugged with a Treudelenberg's canula After the removal of this tumor the wound in the soft palate was closed with sutures The trachetomy pipe was allowed to remain 24 hours for fear that the wound secretions from the pharynx might enter the trachea and produce a pneumonia

Schoenborn is no longer a believer in the antiseptic properties of iodoform, as he has seen the staphylococcus aureus grown luxuriantly upon a culture containing this substance He attributes to it, however, other valuable properties, which act salutary in the process of wound healing, the most important one being that it keeps the wound dry, and in doing so acts indirectly as an antiseptic

In the evening I met Professor Leube and Professor Naunyn at Professor Schoenborn's house, where dinner was served, and a variety of wines sampled German professors, when behind the official curtain, appear to enjoy life as well as the average man outside of the medical profession If Professor Leube is so liberal in diet with his patients as he was with himself that evening, he would experience some difficulty in emptying their stomachs, even seven hours after mealtime The old saying, that "preaching is easier than practice," was verified on this occasion, and we left the house of our pleasant host and hostess, feeling at peace with ourselves and the entire outer world, and conscious that we had spent a most interesting and pleasant evening In my next letter I expect to give you a description of how to cure surgical tuberculosis à la Koenig N SENN

MISCELLANEOUS.

EBERTH'S RODS IN TYPHOID STOOLS —In the *Vratch*, No 22, 1887, p 438, Dr G O Shpolansky, of the Odessa Town Hospital, writes that he and Dr N A Stroganoff, prosector of the same hospital, have examined bacterioscopically stools in 96 cases of enteric fever, with the object of solving the following two questions of paramount practical importance 1 Whether Eberth's microbes are present in all cases of the disease or not? and 2 Whether the microbes are still present in the stools of convalescent patients? The main outcome of their researches may be summarized thus The typhoid bacilli were found in 90 of 96 cases Of those examined, 88 recovered and 8 died In one of the latter no bacilli could be detected in the stools during life In one of three convalescent patients examined no bacilli were found after the temperature had finally returned to the normal range In the remaining two the microbes were still daily discovered for nine and fifteen days respectively after the defervescence In view of the facts stated under the first head, a bacterioscopic examination of the stools should be undertaken in every case where any suspicion as to typhoid fever may arise, and in consequence of those adduced under the second, the stools of the patients recovering from enteric fever cannot be considered innocuous for at least fifteen days after the defervescence —*British Medical Journal*, June 25, 1887

THE ENGLISH PASTEUR COMMISSION —The report of the Committee on Hydrophobia has been recently issued It contains experimental and other evidence which strongly supports the theoretical views of Pasteur and their practical application

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U S ARMY, FROM JULY 2, 1887, TO JULY 8, 1887

Major Wm S Tremaine, Surgeon, ordered for examination by Army Retiring Board, at Governor's Island, N Y Harbor S O 151, A G O, July 1, 1887

Capt J O Skinner, Asst Surgeon, granted leave of absence for four months, on surgeon's certificate of disability S O 151, A G O, July 1, 1887

First Lieut H S T Harris, Asst Surgeon, will be relieved from duty at Ft Ringgold, Tex, upon the return of Asst Surgeon W T Carter, and will then report to commanding officer at Ft McIntosh, Tex, for duty S O 73, Dept Texas, June 27, 1887

Capt Geo T Beall, Medical Storekeeper, granted four months' leave of absence S O 150, A G O, June 30, 1887

Capt A V Cherbonnier, Medical Storekeeper, directed to take charge of office and perform duties of acting Asst Medical Purveyor in St Louis, Mo, during absence on leave of Capt Geo T Beall, Medical Storekeeper, now performing those duties S G 150, A G O, June 30, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING JULY 9, 1887

Medical Inspector A Hudson, detached from the "Trenton" and wait orders

Medical Inspector W K Scofield, ordered to relieve Medical Inspector Hudson on the "Trenton"

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING JULY 2, 1887

P A Surgeon S T Armstrong, relieved from duty at Marine Hospital, Memphis, Tenn, ordered to Marine Hospital, New York, N Y June 27, 1887

P A Surgeon C T Peckham, relieved from duty at Marine Hospital, Wilmington, N C, ordered to Marine Hospital, Memphis, Tenn June 27, 1887

P A Surgeon A Glennan, ordered to revenue cutter "Crawford" for temporary duty June 30, 1887

Asst Surgeon S D Brooks, ordered to examination for promotion June 27, 1887 Relieved from duty at Evansville, Ind, ordered to Marine Hospital at Wilmington, N C June 27, 1887

INTRA-UTERINE THERAPEUTICS

Delivered before the Section on Obstetrics and Gynecology, at the Thirty eighth Annual Meeting of the American Medical Association held at Chicago, June 7 10, 1887

BY W S CALDWELL, M D,

OF FREEPORT, ILL

There is no subject in the whole domain of medicine that one approaches with more hesitation than the one to which I propose to call your attention for a short time to day In the treatment of every organ of the human body, and in the management of every disease in the nosology, we as doctors are proverbially at variance, but in the therapeutics of no other portion of the human body do we stand at such antipodes as in that of the intra uterine surface Some of our best writers regard the whole inner surface of the womb as a forbidden ground, to be avoided entirely, while others treat and manipulate it as they would any other portion of the body

Perhaps I shall not be able to say anything new, or advance a single idea not already known to day, but having spent four years of the last twenty in Europe looking after what pertained to my profession, perhaps a report of my observations gained in this manner, together with thirty years' personal experience, may embody some facts that will repay you for the time I shall occupy your attention

Among the most indelible impressions which I received as a part of my early medical education, and which influenced my practice in a marked degree for the first decade after I began active work, was the horror of the use of the obstetrical forceps, and a fear of the introduction of an instrument of any kind into the uterine cavity To say that I can count a score of mothers and twice as many children whose lives were sacrificed as a result of my early fear of the forceps, is no exaggeration, and while a revolution in this domain of medicine has well nigh swept over the entire professional mind, and perhaps carried us too far in an opposite direction, I am convinced that a great majority of physicians of this country and of Great Britain hold the intra uterine cavity in such profound awe that a large number of women are allowed to live a miserable existence, and are perhaps consigned to a premature grave, on account of the teachings that our best men gave a few years ago, and which are now held as orthodox ideas by many of the leading men who practice medicine in English-speaking countries to day

To sound the sentiment of the profession on the subject of intra-uterine medication, I issued, early in April last, 200 circulars, and sent out to the leading members of the profession throughout the United States, propounding the three following questions

Question 1 —Under what circumstances do you use an intra uterine injection *immediately* following delivery in child birth, and what medicine do you use, and of what strength?

Question 2 —In the puerperal processes following child birth, do you use intra uterine injections, and if so, what are your indications for the use of the same, and what remedies do you use?

Question 3 —Are you in the habit of using the curette, intra uterine injections, or other forms of medication to the intra uterine surface in diseases of the womb not immediately following child birth, and not connected directly with child-bearing?

To these questions I received over one hundred replies More than one half of those who answered say that they never use intra uterine injections of any kind, or under any circumstances

Prof Parvin says *First* In post partum hæmorrhage, whether primary or secondary, hot water uterine injections constitute one of the most efficient means of treatment, these injections are not necessary in the majority of cases, but in some they are

Second In case of retained placenta, whether adherent or not, but in which it is necessary to introduce the hand into the uterus, an antiseptic uterine injection should follow, such injection ought likewise to be used after the removal of a dead and decomposing fœtus In all cases where the hand is passed into the naked uterus, I mean the organ after complete delivery, as is necessary in some cases of post partum hæmorrhage, I should subsequently wash out the uterus with an antiseptic solution

The occurrence of puerperal septicæmia is an unequivocal indication, in my mind, for antiseptic injections in the uterus, these injections being usually 1 to 2000 (corrosive sublimate and water), and repeated twice in the 24 hours, a Bozeman catheter being employed, in some cases I use a 5 per cent carbolic acid solution If the uterus does not contract fully under the injection so as to chase out the corrosive solution, I compress it, and I also wash out the vagina with sterilized—that is, boiled—water, so that practically none of the solution remains either in the uterus or in the vagina for slow absorption, as

before taking this precaution I have seen some cases of mercurial poisoning follow such injections When temperature and pulse fall I cease the injections It is a terrible mistake to wait until the lochial discharge becomes offensive, or to first try merely vaginal injections Strike the evil in its abode and in its beginning by antiseptic intra uterine injections, and I believe almost every case of puerperal septicæmia can be certainly and promptly cured, and usually without employing constitutional treatment to any great extent, antiseptic injections into the uterus constitute the causal, the essential treatment of the disease

The curette, or Emmet's curette forceps, I have had occasion to use in many instances of incomplete abortion in the early months, most of the cases of menorrhagia or metrorrhagia consequent upon disease of the endometrium that have come under my care, have had their origin in an abortion Nevertheless, there are other cases Some years ago I had the terrible pain of seeing a patient die from an intra uterine injection of an iron solution given to arrest the hæmorrhage from fibroids, and I have never since used such injection except in the puerperal uterus Local liquid applications, as of iodine, carbolic acid, and other solutions, I have frequently made to the cervical canal and to the uterine cavity, and believe such treatment should not be abandoned

Dr DeLaskie Miller says *First* I never advise intra-uterine injections immediately after delivery merely because the labor is completed Hot water injections are sometimes useful in post-partum hæmorrhage

Second In septicæmia with offensive discharge, carbolized water

Third I use the curette when hæmorrhage or unhealthy discharges are caused by disease of, or by growths from, the endometrium

Dr Paul Mundé says *First* Injections of ice-water and vinegar in certain cases of post-partum hæmorrhage It is usually proper to wash out the uterus after the birth of a macerated child or an operation which has necessitated the passage of the hand or instruments into the uterine cavity

Second In cases of puerperal fever where the infection can be shown to proceed from the uterus, or where fever follows the birth of a macerated child, or operative procedures in which the hand or instruments have been introduced into the uterine cavity, where there is a fetid discharge which persists in spite of vaginal douches, where the uterus is large and flabby, or where we have reasons to suspect the presence of decomposing bits of placenta or membrane within its cavity The fluid used may be boiled water, or a 1-10,000 corr sublimate solution

Third Yes Chronic endometrites, uterine hæmorrhage, subinvolution or hyperplasia, intra uterine vegetation or malignant disease, defective development Means used are the curette, astringents, styptics, caustics, electricity

Dr W H Byford says In answer to the third question I do not use injections into the cavity of the uterus in non puerperal cases I use the dull curette in granular degeneration of the mucous membrane attended with menorrhagia

Dr C D Palmer says *First* I do not condemn all intra-uterine treatment Think highly of it at times, but do not use it so often as I did in former years

Second Use intra uterine injection immediately after delivery, when child is dead, putrid, and at times after intra uterine manual or instrumental manipulation Use bi delinde 1 8000 or carbolic acid one-half of one per cent solution

Third Use intra uterine injection after delivery when septic symptoms are present or threatened, and have reason to believe cause is within uterus Use curette and intra-uterine medication (not injection), for chronic intra-uterine diseases The former more often than latter

Dr H J Garrigues says *First* When it has been necessary to introduce fingers, hand or instrument inside of the uterus

Second In case of a macerated fœtus I use 1 to 4000 bichloride of mercury solution, using two or three pints In answer to your second question I would say I use injections in case of sepsis, especially puerperal diphtheria, I use 1 to 4000 bichloride, using two to three pints every 24 hours A pencil containing 100 grains of iodoform is introduced into the cavity after the injection, cauterization with the chloride of zinc, 50 per cent

About one fourth of my answers show that the parties only use intra uterine injections following labor to arrest hæmorrhage, using for this purpose hot and cold water, solution of perchloride of iron, zinc, iodine, vinegar, and the like

Some of the men who answered me must have been born under a lucky star, for several of them aver that during an extensive practice extending over a period of from twenty to thirty years they have never lost a patient from any puerperal process This certainly contrasts most markedly with my own experience, and while the results achieved in the lying in institutions of this country and Europe are most brilliant as far as the mortality to both mother and child are concerned, I am of the firm belief that in private practice there is still much to be accomplished before we have done all for our patients that our duty demands, and that the new lights shed upon this branch of medicine will enable us to do

Considering, first, the question of intra uterine injections following immediately after child-birth, we are informed that even as far back as the time of Hippocrates and Galen this procedure was resorted to as a means of combatting uterine hæmorrhage and to facilitate the expulsion of the retained secundines But this practice, like many others that were conceived and followed out by these eminent fathers in medicine, found but little favor in the ages that succeeded them, so we may say that this practice might be classed as one of the lost arts until revived in the latter part of the last century by Recobin He strenuously advocated the use of cold water as an intra-uterine injection in cases of retained placenta or violent hæmorrhage Levret and Baudelocque were also warm advocates of this practice But all uses made of intra-uterine injections, up to the lat

ter half of this century, were designed mainly to act mechanically or simply as an astringent to arrest the flow of blood Not until the last half of the present century, when the germ theories of Pasteur and Koch, and the antiseptic precautions advocated by Mr Lister, had gained a foothold in the minds of the profession, do we find any definite plans given to guide us in the use of injections into the uterine cavity

Well do I remember a generation ago being counseled by the same man to always leave my forceps at home, for fear of being tempted to use them too early, teaching me at the same time that puerperal fever was a zymotic disease in no way communicable, and ridiculing all doctrines as to its contagious character

Semmelweis, in May, 1847, announced the doctrine of the identity of child bed fever with other pyemic processes, and recommended the hands to be washed with chloride water, and afterwards on account of its cheapness the chloride of lime (10 oz to 2 lbs of water), as a disinfectant This, I believe, is the beginning of what has developed into our modern antiseptic idea of the management of child birth

Retzius, at Stockholm, in 1849, to prevent the spread and development of the puerperal processes used astringent injections, *per vaginam*, touched the abraided surfaces of the same with tincture of iodine and used nitrate of silver in strong solution as an intra uterine injection In 1855 Braun and Spaeth both recommended the use of a strong solution of alum in the womb in case of fever following birth, and where there was a foul discharge In 1871 Mayhofer found in the fœted lochia of patients suffering from child-bed processes vibrios, which he believed to be the specific germ that caused the disease These he cultivated in an ammoniacal solution, and injecting them into the genitals of the female rabbit, the animals died of the symptoms and with the lesions found in the human subject Later Waldeyer, Orth, Heiberg, Spillmann, and others, made investigations confirming these experiments In 1877 M Pasteur communicated to the Academy of Medicine, of Paris, his investigations as to the specific character of the microbe of puerperal fever, and while he and other observers recognized certain forms of microorganism that accompany the suppurative discharge in the ordinary cases of child bearing, these latter forms of organic life produce no profound symptoms upon the constitution of the patient, and were never found in the general mass of the blood itself On the other hand, the true materies morbi of genuine puerperal fever was always found in the circulations, thus producing a series of most profound constitutional disturbances The world over Mr Lister is recognized as the father of antiseptic surgery It is in Germany that one finds Listerism practiced with the minutæ and detail that puts far in the back-ground anything that the father of antisepsis practices to day at Kings College Hospital As a proof of this you would only have to witness the surgery of Bergmann, at Berlin, or Volkmann, at Halle

Laying hold of this new theory as to the nature of all puerperal processes with the avidity that characterizes the German race, we find for a decade that antiseptic intra uterine injections were not only used as a means of combatting the morbid processes following child birth in nearly all the German hospitals, but that every woman who gave birth to a child had her uterus washed out as a prophylactic measure to prevent the possibility of her becoming infected by the germ that this precaution was intended to destroy Experience, however, soon demonstrated that this practice was not a judicious one, and that interference where no morbific symptoms were present was not warranted

In 1882 Dr Fischel published a lengthy article giving the results of experiments made on a large number of lying in women in the wards of Prof Breisky, in Prague The result of these observations went to show that when intra uterine therapeutics were used as a prophylactic agent in all cases of child birth, the results were less favorable than where they were not used at all But after limiting their use to such cases as were attacked with symptoms of child bed fever, viz increase of temperature and pulse frequency, he reduced the mortality of septic fever in child bed to 0 21 per cent With Breisky the whole subject of intra uterine treatment rests upon the theory pretty generally accepted to day of the germ theory of the different puerperal processes, and the infection of the parts through the channel of open wounds, by means of germs contained in the atmospheric air He says that such have been the brilliant results of this new treatment, that the cases observed by the older practitioners and recorded in the books, where, in spite of all treatment, the patient sinks and dies within a few days of an overpowering and generally diffused septic process, are now almost never observed, and are unknown in the practice of the younger members of the profession

Starting out with the proposition that we may do harm with our treatment if improperly used, the rule laid down is this that, while many patients who have a temperature of 38° or even 40° C may come out all right, yet our observation teaches us that we can never depend upon such a result, and that we often see cases that begin very mild, but have repeated chills, and finally die of a septic process in spite of all that can be done for their relief Therefore, when the temperature rises to 38 2° we should interfere

Among the important points to be noted in the use of local antiseptics in child bed fever is, first, if possible, to determine at what part in the genital track the *materies morbi* gain access to the system This cannot always be done, but, as the vagina must be the channel through which all foul matters pass out, we should render this perfectly aseptic A failure to do the work well will often be observed in a case like this A patient has a foul smelling discharge from the vagina To remedy this, though the patient has no fever, you use an ordinary vaginal injection or direct a nurse to do so At once your patient is taken with a chill, and a high fever follows How is this to be explained? Soon after confinement nature throws out on the abraded surfaces a layer of plastic lymph You have washed this away, and rendered these

surfaces tenfold more liable to absorb morbid products than they were before If you use an injection at all, do so most thoroughly Hunt out the abraded surfaces on the vagina and apply, after drying them thoroughly, tincture of iodine, which is one of the best known antiseptics, for, while it produces no ill effects upon the tissues, it renders them free from the liability to absorb the secretions

In the matter of intra uterine injections, if you use an injection strong enough to kill the organic germ, and remove at the same time all débris from the uterine cavity, it is not necessary to repeat the same For this purpose Breisky uses a 5 per cent solution of carbolic acid, or a strong solution of chloride of lime But the principal danger from intra uterine injections is the liability of carrying with your tube foul matters from the vagina into the uterus, and hence the absolute necessity of disinfecting the vagina as a primary step in the operation

Dr E Ehrendorfer, assistant to Prof Spath, in Vienna, began in 1881 experiments in the intra uterine use of iodoform in child bed He begins his article, entitled "Ueber die Verwendung der Iodoformstabschen bie der intra uterine Nachbehandlung in Wachenbette," with the remark that, although iodoform has long been recognized as one of the best antiseptics in surgery, its mode of application to the uterine surface was a difficult problem *First*, the introduction of the powder into the womb was a difficult process, then again the use of a suppository of cocoa butter was a partial failure on account of the rapidity with which the menstruum was dissolved, and its consequent rapid passage out of the womb and vagina To circumvent this difficulty a bacillus (suppository Stabschen, as the Germans call it) was made after the following formula

Iodoform	grms 20
Gum arabic	
Glycerine	
Amylum pura āā	200
Make 3 suppositories	

The manner of using these was first to wash out the uterus thoroughly with a 2 per cent solution of carbolic acid, and then, after the womb is well contracted, to dip the Stabschen in a solution of carbolic acid, grasp it with a pair of curved forceps, and, using two fingers of one hand as a guide, to pass it into the womb The indications for the use of this agent are first, after all operations that require the introduction of the hand or any instrument into the uterine cavity *Second*, it should be used in every case in which there is a rise of temperature after child birth, if it be evident that such increase of bodily heat has its foundation in a morbid process originating in the womb

Some of the most brilliant results from the use of iodoform as an antiseptic in uterine surgery I saw illustrated in the service of the lamented Prof Schroeder, of Berlin, during the past year I saw in one case an intra uterine fibroid weighing four pounds, and another of two pounds, removed *per vaginam* These masses were not pediculated, but occupied a large part of the intra uterine surface, and had to be cut away piece meal, the operation lasting from one to two hours, and yet both these patients recovered without any profound constitutional disturbance When I contrast these results with my own experience, having lost two patients when this operation was much less formidable, and that evidently not from any special violence done to the womb itself, or to the surrounding organs, but from a septicæmia that followed, it has produced a firm conviction in my mind of the value of this agent as an antiseptic in this domain of surgery

Much discussion has arisen of late as to the likelihood of the occurrence of iodoform poisoning when this drug is applied to the uterine surface The drug had been used during a period of two years when I was last a student in the lying-in hospital in Vienna. Dr Ehrendorfer says that when even as much as 10 grains of it was used in a single Stabschen, he never saw any toxic effects manifested Konig, after a long series of experiments, says that he never saw iodoform poisoning occur when less than 10 grains were used Kowalski, in a paper lately read before the Vienna Medical Society, says that he has tried this agent in 326 cases as an intra uterine application, without a single case of poisoning from the drug He used it besides, as an experiment, upon his own person, and found that when he took no more than 6 grains in the twenty-four hours, no intoxication occurred, but even a much smaller dose caused toxic effects if long continued, showing the drug to be cumulative in its action

To illustrate the manner of managing a not infrequent class of cases in midwifery, I copy the following history from my notebook A woman, 40 years of age, was brought into Carl Braun's wards at 10 A M, August 15, 1886 She had had some uterine pains, and had flooded profusely for twenty-four hours before her entry Examination showed a partial placenta prævia, but, as she was not losing blood very rapidly, it was thought best not to interfere except to wash out the vagina and assist uterine contractions by massage The fœtal heart could not be heard Her temperature on admission was 38 2° C At 11 P M it was 39 5 At 6 A M, August 16, the child was delivered by version, dead At this time her temperature was 41°, and for this reason was interference resorted to, not on account of loss of blood At 7 A M she was placed upon the table, the vagina first well washed out with a bichloride solution, 1 4,000, then the womb irrigated with the same, then the uterine surface well scraped out with a large blunt curette bringing away some shreds of membrane and some clots The womb was now again irrigated with the mercurial solution, 2 litres being used, and following this the organ was washed out with a solution of thymol, 1 1 000, the iodoform Stabschen carried into the womb and the patient put to bed At 7 P M, twelve hours later, her temperature had fallen to 37 5°, and at 11 P M was only 36 6°, and from that time on the patient made an uninterrupted recovery I watched this case with great interest for I remembered when a student of Braun's in 1878 having heard him say that if a woman's temperature *rose to* 40° C within twenty-four hours after her delivery, she would *positively* die, for the reason that it showed

an ante partum infection, to which he claimed the patients uniformly succumbed The brilliant result in the case just cited shows how antiseptic intra uterine treatment has revolutionized all this

To illustrate the management of another case I will draw again from my note book A poor woman living a distance of fifty miles from Vienna was taken in labor with the complication of an arm presentation Physicians near by made an ineffectual effort at version, but not succeeding, they dispatched her by rail to the lying in wards of Karl Braun When brought in for examination it was found that the abortive attempts at turning had resulted in a laceration of the cervix up to the body of the uterus and within the narrowest limits of the peritoneum itself From this the poor woman had bled until she was almost *in extremis* Braun's blunt hook was used to decapitate the child—which was already dead—and delivery was effected without great difficulty The parts were disinfected by the injection into the vagina and uterus, of a 5 per cent solution of carbolic acid, followed by a 1 1000 thymol injection

The laceration in the womb was brought together by three silk sutures, the iodoform Stabschen was introduced and the woman put to bed Though extremely exsanguinated this woman made an uninterrupted and excellent recovery

The point I wish to make is this, and bring these two cases to illustrate my idea, that where intra uterine injections are used after delivery because it has been found necessary to institute any manual or instrumental procedure, and where there is no evidence of an ante partum infection manifesting itself, by an increase of temperature and the like, it is not necessary to resort to the bichloride of mercury injections but it is better to use either a 5 per cent solution of carbolic acid or a 1 1000 thymol injection, using the iodoform Stabschen in either case after the injection

Coming now to the consideration of the second question in my circular, that is, under what circumstances should we use intra uterine injections in the puerperal processes, and what should we use? They should be used, as I have intimated, whenever the temperature rises to 38 5° and where such rise is evidently caused by some morbid process going on in the genital track That the bichloride of mercury should be used not stronger than 1 4000, that usually the blunt curette should be used to remove any portion of membrane or clots, that the mercurial solution should be again repeated, and then the womb washed out with simple hot water or thymol solution to wash away any redundancy of the corrosive sublimate The iodoform Stabschen should be used as a last part of the operation, whatever solution is used as the injection

Now, if this work be well done its repetition is generally unneccessary I must take issue with some of the best men who answered my circular—and some of them are the best authorities in the United States—on this point, many of them recommending the repetition of the bichloride solution as often as two or three times a day for days together This I believe to be a dangerous procedure unless great care be used to wash away each time any redundancy of the mercurial solution Again, these repetitions are unnecessary if they are used early and are well used

If your local treatment be not followed by an amelioration of the constitutional symptoms, you may be assured that the process has passed beyond the limit of a local one, and has become a generalized infection over which your antiseptic local treatment will exercise no influence

In passing to the consideration of the third division of my subject, viz, the application of medicines to the inner surface of the womb at a time not connected with child bearing or immediately following that act, I will not attempt to even give a *resume* of the different agents that have been used for this purpose, or of their mode of application, but will discuss the question mainly in connection with the use of the curette and certain adjuncts as a part of such treatment

Here we enter a field where the profession are even more at variance than in the matter of intra uterine medications in child birth and the diseased processes immediately following that act In perusing the works of some of our best authors on gynæcology one is struck by the fact that, while they recommend the greatest caution in the use of the uterine sound, they do not hesitate to advise the swabbing out of the uterine canal with pure tincture of iodine, carbolic acid, nitric acid, and the dropping in at hazard upon this delicate surface portions of pure nitrate of silver of considerable size To my mind this inconsistency is easily explained For instance, that man whom you will all recognize when I say that he is the greatest authority on gynæcology, living or dead, of this or any other country, tells us to use the uterine sound without a speculum and without giving us any directions as to the disinfection of the vaginal track before its use Now what is one of the accidents that may follow this simple procedure, even if done with the greatest care? It is the carrying into the uterine cavity of organic germs that are likely to be found in the vaginal track and thus setting up of a morbid process from bacterial infection Has not nearly every one who listens to me had an experience something like this After a severe labor you find it necessary to use the catheter on your patient one or more times From this time on the woman is troubled with frequent micturition, vesical tenesmus and the like Examine her urine with a microscope and what do you find? It is loaded with bacterial germs How now did they gain access to the bladder? They were carried there by your catheter from the vaginal walls In the same way you are likely to carry these bodies from the vagina to the uterine cavity through the medium of your sound

Therefore, you should never use the catheter in the female without first cleansing the parts with which your instrument comes in contact, and should never introduce a uterine sound or any other instrument into the womb until you have first thoroughly disinfected the vaginal track

I believe, also, that if this canal was thoroughly disinfected before the use of the obstetrical forceps, many of the accidents that follow such operations

U. M. H. S. LIBRARY.

would be obviated Récamier, who introduced the practice of curettage, into France, was followed by many warm disciples both in that and other countries To scrape out the womb was in fact the rage for a decade or more The great Nélaton caught the infection, and operated on a large number of women, until two of his patients died as a result of the operation From this time on he abandoned a procedure that he became convinced was eminently dangerous to life Prof Gilleau, of Hôtel Dieu, himself a pupil of Nélaton, inherited a strong prejudice against this instrument from his old master, and yet I have seen him use it with a boldness that would almost rival the practice of Martin himself In a clinical lecture on this subject he says "The whole question of the safety or danger of the operation hinges on the point as to whether you perform it perfectly antiseptically or not"

I have been a pupil at three different times of Martin's, in Berlin, and when I saw him first scrape out, wash out and treat the uterine surface in the manner in which he does I felt a feeling of horror run through me akin to that which one would naturally experience at seeing an operation performed that was considered most likely to result in the death of the unfortunate patient Some years elapsed after seeing these operations performed, during which time I saw treated a large number of gynæcological cases, but it was not until I had seen them frequently repeated, and was able to see some of the good results following their use at my last visit to Berlin, that I became an advocate of the practice My confidence in the treatment had its foundation in the conviction that its dangers were averted by the observance of the most perfect antiseptic precautions, and since my return from Europe this spring I have treated several cases with apparently the most happy results

Having determined to institute our intra uterine treatment, among the first questions presented as a preliminary step in the procedure is the necessity or advisability of using some means to dilate the uterine canal In a vast majority of cases I hold mechanical dilatation to be unnecessary The failure to get an instrument into the womb does not usually arise from a narrowing of any part of the track but from a deviation in the direction of the canal in some part of its course To overcome this it is only necessary to catch the anterior lip of the womb and produce sufficient traction to straighten the channel I show here the very ingenious manner of practicing this maneuver by the late Prof Bandl

If it be necessary to dilate the womb, I believe that it is generally better and safer to accomplish this by using Hegar's dilators than by any form of tent, on account of the liability of the use of the latter to be followed by septic infection

Having spoken of the use of the curette and its dangers, we come now to the subject of intra uterine injections in general gynecological practice Among the possible dangers that may complicate this operation is the passage of the fluid used through the Fallopian tubes into the peritoneal cavity That the dangers of this accident have been greatly exaggerated I am well convinced In a paper read before the Scientific Congress of France at Havre, in 1878, Prof Gallard demonstrated that the fears that we have entertained as to the entrance of fluids injected into the uterus via the Fallopian tubes into the peritoneal cavity are entirely unfounded In a series of experiments it was shown that in the cadaver it was not possible to force water into the uterus with sufficient force to cause it to enter the peritoneal cavity without first tying the canula used firmly in the cervical canal by passing a ligature around the neck of the womb Gallard says that the size of the internal os may be fixed as that of a No 12 Charriere, and therefore if we use a No, 10 no danger can arise Dr Braun's instrument, which I show you, I consider the very best one for this purpose, as it differs from that of Bozeman by having the channel of exit several times larger than that by which the fluid enters the uterine cavity No syringe should be used as a means of forcing any fluid into the womb, but an irrigator, in which the pressure can be most accurately regulated by the height to which you raise your reservoir As a preliminary step I would always advise the washing out of the womb with some antiseptic fluid before the use of the curette

While the curettage of the inner surface of the womb for the relief of obstinate hæmorrhage, and for the removal of retained portions of the secundines after abortion, is a well recognized and orthodox procedure, I believe that its application can be extended to a much larger field in well selected cases Take the case of a woman who has borne children, her womb measures from one half to one inch more than normal, there is no extensive laceration at either side of the cervix, yet the mucous membrane of the canal is eroded and everted around the entire cervical canal She has a profuse leucorrhœal discharge, and her menses may be either scant or profuse If I ask ten of the best men who listen to me how they would treat such a case, I would be likely to get ten different modes of management in answer to my question, and after following out each recommendation, I would probably find my patient but little better than when I began the treatment of her case The average man will never see anything in this case farther than the changes in and around the cervical canal, and his treatment is generally an entire failure, for the facts are that the entire mucous surface of the womb is diseased, and any treatment, to be successful, must be applied to this entire track The mucous follicles are immensely enlarged, and secrete an abundance of an abnormal secretion

In a case like this, if you will carefully use the curette to the entire intra uterine surface, removing these enlarged follicles, and then from time to time irrigate the womb with a mild astringent wash, you will be astonished to see what progress your case will make toward recovery If there be a considerable relative elongation and enlargement of the cervix I would perform, as a part of this treatment, the amputation of the lower portion of the cervix uteri

It is necessary, of course, before instituting any intra uterine treatment, to convince yourself that there is no fixation of the womb or a peri uterine infiltration that complicates the case Under e ther of

these conditions any manipulation of the organ may light up a latent diseased process, and be followed by consequences of a most unpleasant character

DISCUSSION

DR G A MOSES, of St Louis The paper just read, which so admirably states the present advanced stage of science for the proper treatment of women suffering from puerperal disease of septic origin, leaves scarcely anything to be said We must agree entirely with the propositions made by the gentleman, but I think it probable we are at extremes in some of the procedures advised For example, I can scarcely see the possibility of infection by the passage of the catheter, provided it be clean before introducing it into the bladder, on account of the slight contact with the parts which takes place The reason I refer to this is that I think we are disposed to attribute to the wrong cause inflammations which occur under these circumstances We should look deeper for the causes of diseases that are presumed to be conveyed to the parts by our carelessness, which I am satisfied is not always the case As regards the fear of conveying germs into the vagina by the use of forceps or any other instrument that may be necessary during labor, the vagina is from the beginning more or less filled with discharges which I take to be most thoroughly antiseptic, unless there has been some preexisting disease, and for the purpose of using the hand or instruments I cannot see that it is ordinarily advisable to douche the vagina with strong antiseptic fluids It has not been my practice, because I think there would be more harm than benefit Of course the strictest antiseptic precautions should be observed in regard to the hands, it would be criminal to do otherwise One other point in relation to the method of curetting, the value of this mode of treatment is undoubted, and I agree in the method of curetting and the instrument exhibited, which I vastly prefer for efficacy and satisfactory work to any of the so called blunt curettes Where it is necessary to remove any thickness of mucous membrane we may desire, I have never been satisfied with the slight work that the ordinary really blunt curette has done Where I wish to remove diseased membrane or affect the cause of inflammation, I prefer an instrument modeled something after the one exhibited—a hollow spoon, with which one can remove thoroughly all the diseased parts, and can, by withdrawal of the instrument from time to time, examine the parts which are removed As a matter of course antiseptic solutions should be used for cleansing the parts, and the after treatment following the curetting should be done in the manner described I agree with the gentleman that antiseptic douches for irrigation should be used at once and that no repitition is ordinarily necessary The employment of a too mild, or inefficient, or imperfect, irrigation is worse than useless, it is temporizing and encouraging disturbances which may prove fatal Therefore, a thorough irrigation of the puerperal uterus with a disinfectant solution should be used at first I think the author did well to impress upon us the necessity of the use of a comparatively innocuous wash after the injections of the stronger solution of sublimate If this is always done and we do not allow any portion of the sublimate solution to remain we will entirely avoid any of the mercurial poisonings which have been so frequently urged against the value of this method

DR H O MARCY, of Boston As long ago as 1881 I was heard on this topic Three years ago I reviewed the ground carefully I am glad to hear the paper, and I am also glad to hear the remarks of Dr Moses, that it is better never to do half heartedly this work I believe the greatest danger in antiseptics to day lies in half doing If there is a greater reason for reviewing this subject, it would be this If an antiseptic application is to be made to the uterine cavity the reason for its making is that the cavity is septic, and that is the reason why uterine injections ordinarily are to be recommended. There is no part of the body where the septic processes go on more rapidly It behooves us to be carefully on the watch I would like to emphasize the wisdom of the careful observation of the thermometer The moment that the temperature rises remember there is danger I would again emphasize this In all obstetric operations insure a clean vagina I believe the vagina is septic and there are always some germs in it If you find that there is danger, be sure you are thorough, hence the curetting and removal of these semi-decayed or necrosed portions of tissue we call septic It can be removed carefully, and then we have the condition of an aseptic cavity But remember, that oftentimes you will find the danger is beyond your local point and your septic fever is not less than the regions of the enemy passed beyond the uterine chamber

Again, in regard to the applications in the uterus in a non pregnant state, the curetting I believe to be not only very safe but very wise In the last twelve months I have curetted 100 uterine cavities, and probably more If we do this thing let us do it in a whole hearted, conscientious way, understanding the reason why we do it and understanding that we are safe if we use bichloride of mercury I have not the slightest objection to using a solution of 1 1000 in the uterine cavity, but I earnestly protest against any carelessness in this matter I have made use of iodoform year after year, and I have never seen a case in which I thought my patient was injured from either carbolic acid, bichloride of mercury or iodoform

HAY FEVER

The First Prize Essay of the United States Hay Fever Association for 1887

BY SETH S BISHOP, M D,

SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY TO THE SOUTH SIDE FREE DISPENSARY, ETC CHICAGO, ILL

The limitation placed upon the length of this essay is my apology for the incomplete manner in which the subject is treated Believing that those

for whom this is written will be principally interested in the cause and treatment of the disease, I have devoted most of the paper to the consideration of these topics

Pathology—Hay fever is a functional nervous disease No organic change has ever been found in the nervous system to which the peculiar suffering in this malady could be attributed The symptoms are manifestations of exaggerated functional activity

There are three factors which satisfactorily account for all the phenomena presented by a paroxysm of hay fever *First*, highly susceptible nerve centres, *secondly*, over sensitive nerve ends, and *thirdly*, the presence of one of a large number of exciting causes The conclusion that this is a functional nervous disease is a logical one, based on anatomical, physiological, pathological, and therapeutical facts Let us examine these *seriatim*

One of the centres of the sympathetic nervous system—the spheno-palatine ganglion—supplies branches to the lining membrane of the nose, throat, soft palate, and Eustachian tube It possesses a sensory, a motor, and a sympathetic root It is connected with the pneumogastric and facial nerves, and through its numerous connections an intimate sympathetic relation is established between the nose, throat, ear, larynx, and bronchial tubes Sympathetic, from the Greek words σύν and πα'θος, meaning suffering together, precisely expresses it Removal of this ganglion causes a severe catarrhal condition of the nasal mucous membrane This membrane is continuous with that which lines the nasal duct and eyelids, the throat, Eustachian tube, middle ear, larynx, trachea, and bronchial tubes A congestion started in one portion of this membrane may extend to other parts, as the inflammation in erysipelas may spread over the body

The nerve theory is not incompatible with the fact that a diseased membrane may be found in the nose after many recurrences of congestion of the parts through years of suffering Neither is it controverted by the excellent general health and superior intellectual endowment of this class of patients Mental workers, such as authors, physicians and clergymen, constitute this class, while manual laborers seem to be rarely affected I have met with but two hay fever cases in a dispensary practice affording opportunities for the observation of several thousand cases of various diseases, in a climate prolific of nose and throat affections

I will enumerate, briefly, several arguments in support of the nerve theory The nervous temperament of the sufferers, the hereditary character of the disease, the identity of its different forms, its similarity to asthma, its periodicity, and the surprising suddenness of its coming and going, the stimulant, tonic, and sedative character of the best remedies—nerve remedies, the effect of mental impressions and physical exertion in preventing and arresting attacks All these are suggestive of functional nervous derangement

Predisposing and Aggravating Causes—Heredity and the temperaments classed as nervous are, strictly speaking, the predisposing causes Broadly speaking, whatever diminishes the powers of resistance predisposes one to attacks Most foreign substances which are liable to come in contact with the nasal mucous membrane will provoke paroxysms, inasmuch as the mere contact of a polished silver probe will excite sneezing Dust, pollen, infusoria, dry hot air, cold, damp, or foggy air, smoke, gas, bright light from the sun, electric light, gas light, sunlight reflected from snow, etc, are prolific causes Much may depend on the character of the dust, for this is determined by the geological formation of any given locality So wide is the distribution of dust by the varying currents of the air, that places which would naturally afford immunity from this disease may be visited by storms of noxious foreign pollen A sea voyage is considered a certain cure for an impending attack, but even there the enemy may lurk unseen in the folds of the canvas or clothing, or in the upper currents of the atmosphere Darwin has shown that pollen has been wafted many miles over the Atlantic Showers of pollen have fallen hundreds of miles distant from its native soil Dust may be deposited in curtains, carpets, etc, and be retained for indefinite periods before finding lodgment in the respiratory tract The upper strata of the air may be laden with pollen, as it is at times with volcanic dust, which may be so dense as to darken the sky at great distances from the source of supply These truths illustrate the omnipresent and occult character of the exciting causes

The greatest suffering occurs from May to October, especially in the country, and for the following reasons *First*, at this season the air swarms with the fecundating dust of plants and flowers, *secondly*, the dry, hot air of the country is not moistened during the day except by occasional rains, *thirdly*, the dry surface soil affords the winds a never-failing supply of dust, *fourthly*, one is not protected from the dazzling brilliancy of the sun by tall buildings in the country as he may be while pursuing the avocations of city life The streets of cities are deluged with water in summer, the dust is laid, the air is cooled and moistened by evaporation Great buildings afford protection from the scorching rays of the sun The denser the population the less the vegetation, and the greater the relief to asthmatics and hay fever patients

I desire to lay especial stress upon the irritating effect of dry, hot air It causes great activity of the muciparous follicles, and imposes a heavy burden on the glands to pour out sufficient mucus to keep the membrane moist One must avoid dry heat from stoves and furnaces Much thumbed books and newspapers that are a little musty are exciting causes I have not seen mentioned

Advice to the Sufferers—Treatment—One may take a sea voyage, or visit the White Mountains, or one of the many other well-known resorts, or he must combat the disease with such weapons as our list of palliatives affords

A retreat which relieves one may not be free from all irritants which might affect another I have known places to be recommended as hay fever resorts where some patients suffered severely Mackinaw

and Petosky, Mich , the Lake Superior region, and the mountains of Colorado and California are favorite resorts Many asthmatics experience entire freedom from suffering by changing a country residence for one in the heart of a great city I have known the same change to greatly mitigate attacks of hay-fever, but if the smoke and soot from soft coal are obnoxious, one must avoid a neighborhood of factories, hotels and large restaurants, whose chimneys pollute the air with smoke

Another important preventive measure is the protection of the body from the vicissitudes of the weather Fabrics of vegetable fibre, such as cotton and linen, should not be worn next the skin Animal fibre, such as woolen or silk, favors absorption and evaporation of the perspiration, and keeps the temperature of the surface of the body equable It prevents chilling Woolen is preferable to silk, except in the hottest weather, when thick silk underwear affords more comfort and sufficient protection Another excellent precaution is to have garments brushed daily before wearing them, to remove all dust The air of sleeping and living apartments should be kept pure and moist, and not above 70° F in winter Plenty of sleep should be had The bodily temperature should be modified in hot weather by means of cooling drinks and ices The generous use of these before retiring will reduce the temperature and avert attacks In cold weather the body may be heated and bathed in perspiration by means of a cup or two of hot, strong coffee I have repeatedly observed this simple remedy avert attacks of hay fever, as well as of asthma A glass of wine subserves the same purpose Coca wine has an additional exhilarating effect, but great circumspection must be exercised in recommending these nerve remedies Unfortunately, it is with this class of medicines that pernicious habits are established It is by these nerve stimulants, tonics and sedatives that we conserve and increase the powers of resistance, combat exhaustion, and soothe irritability of the nervous centres

Remedies to prevent enervation should be taken before and during the periods of suffering The most reliable in this class are quinine, iron, strychnine, arsenic, phosphorous, caffeine, and electricity Grindelia robusta has proven so unsatisfactory in my experience that I cannot indorse it In that form of hay fever where there is active or passive congestion of the brain, ergot is indispensable Bromide of soda, for the same purpose and for its tranquilizing effect on the irritable nervous tissue, is preferable to bromide of potash, in that it contains a larger percentage of bromine, is less vitiating to the blood, and is less disagreeable than the potash

It is obvious, from the nature of these medicines, that they should be taken only under the directions of a physician

These remedies suggest the blending, like prismatic colors, of the subjects of preventive and

Palliative Treatment —Quinine in tonic doses may not only prevent attacks, but will greatly mitigate them if taken in doses of two or three grains every two or four hours during the day But quinine in large and continuous doses produces congestion of the middle ear, and probably of the auditory nerve I have had many cases in which there was no room for doubt that it caused permanently impaired hearing and subjective noises The bromides are not less useful during than previous to attacks They not only soothe the irritable nervous centres, but induce refreshing rest—

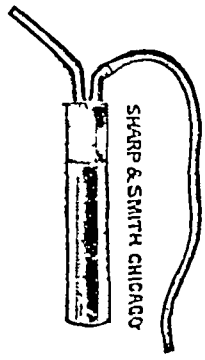
Tired Nature's sweet restorer balmy sleep "

Chloral hydrate alone, or combined with bromide, in bromidia, is more certain still But the dangerous character of chloral, and the peculiar ill effects of both drugs, forbid their indiscriminate use

Better than all other drugs in my experience has been a happy combination of morphia and atropia in easily divisible compressed tablets Not more gratifying results could be expected from palliative medication than I have obtained from this For several years past I have rarely employed morphine in my practice without administering atropia with it, believing that the antidote should go with the poison. The relative proportions which have proved so satisfactory are $\frac{1}{300}$ grain of atropia to ⅛ grain of morphia, $\frac{1}{150}$ grain of atropia to ¼ grain of morphia, $\frac{1}{100}$ grain of atropia to ½ grain of morphia, if this dose were required A larger proportion of atropia in repeated doses is likely to cause a temporary dimness of vision If carefully adapted to any given case I do not believe one need fail to prevent an attack or modify one already begun Where I have been able to administer the remedy myself in the early stage of hay fever or of acute nasal catarrh I have never failed to prevent the development of an attack, or, at least, materially abridge it If the impending attack is a light one, ⅛ grain of morphia should be given at the first premonition If the symptoms disappear, that suffices If they return after a few hours, the dose should be repeated, and in this way the paroxysms should be entirely prevented If the threatening attack promises to be a severe one, I give ⅙ or ¼ grain of morpnia (with atropia always), and I have found it necessary in a profound seizure to give ½ grain before the trouble could be subdued Minimum doses may be better as a rule, but in this malady the reverse is often true. When a small dose may not prevent suffering, a little larger one, to produce a decided impression on the nerves, may be entirely successful Those who are conversant with the physiological action of these drugs will readily understand how perfectly this remedy meets all the indications for treatment It relieves excitability or over susceptibility, and arrests the flux I regret that on account of the necessity of brevity I cannot elaborate this important subject. Wine has often acted like magic in arresting attacks This is indicated in those cases where anæmia of the brain exists It seems to arouse it from lethargy and fortify it against paroxysms Coca may be advantageously used combined with it when there is debility or mental depression Strong coffee is preferable to wine for obvious reasons, but it has the disadvantage of preventing sleep in many cases, while a moderate dose of wine may promote sleep Nitrite of amyl, in five drop doses, inhaled from a

handkerchief, will often relieve attacks, especially if they are accompanied by asthma Aconite should be used in case of fever

Cocaine, in a four or ten per cent solution, applied with a camels'-hair brush, gives speedy relief The patient should never omit clearing the membrane of mucus before applying any local remedy, else the medicine is diluted and prevented from acting on the seat of irritation Better than the solution is a six or ten per cent powder of cocaine and sugar of milk, applied to the nasal cavity with a pocket insufflator or powder-blower, small enough to carry in the vest-pocket, and to be used unnoticed the instant an attack threatens The vulcanite tip of the soft rubber tube should be applied to the lips, when a gentle puff of the breath will blow a cloud of the anæsthetic powder into the nasal cavity, when the hard rubber tube is properly directed This instrument is constructed after my large office insufflator, which is operated by a rubber bulb containing soft-rubber valves The effects of cocaine may last several hours, but repeated applications may be necessary to keep up continuous insensibility of the membrane during prolonged attacks However, it should be known that some persons possess an idiosyncrasy which forbids the use of cocaine The primary action may produce anæsthesia and anæmia of the membrane, regularly, but the blood-vessels may become dilated and remain so, instead of returning to their normal calibre as they do in most cases This condition of secondary hyperæmia is attended with intense hyperæsthesia and all the symptoms of severe hay-fever Fortunately there seem to be few who are so distressed by this remedy, and I have employed it in many cases of various diseases without observing any disagreeable symptoms



Bishop's Pocket Insufflator

Rhigolene spray may be mentioned in connection with cocaine, since they are both useful in producing numbness of the mucous membrane before cauterizing or cutting it Rhigolene will freeze the parts in two seconds, and is even more efficacious than cocaine in rendering an operation bloodless Morphine spray or powder is useful Zinc sulphate and glycerine of tannic acid are beneficial in cases of inflammation or ulceration Inhalation of spirits of camphor and of eucalyptol have proved grateful in light attacks Chloroform and fumes from nitre-paper will often help the asthmatic type

When an attack seems imminent, the determination of blood to the turbinated bodies may be relieved by derivation by means of active muscular exertion,—such as running rapidly up-stairs, putting the muscles of the hands, arms, and legs on the stretch, or practising calisthenic exercises,—anything to cause sudden and strong tension of the muscles and divert the mind In this manner the pent up nervous energy, struggling to escape, finds vent

Operations on the nose are in fashion now They have their good and bad features, like other fashions, but the reason that operative measures for the destruction of the offending mucous membrane and nerve ends in the nose often fail to cure is that the nerves distributed to that part are not the only ones which are over-sensitive Irritants impress the nervous centres through various other channels When the sensitive areas appear to be circumscribed by the limits of the nasal mucous membrane, the destruction of the sensitive areas in that membrane by the galvano cautery, chromic acid, the snare, saw, or knife, may be expected to afford relief Especially is this the case when there is much enlargement of the turbinated tissue, or such deformity of the nasal partition as to cause pressure on the turbinated bodies But so extensive are the connections of the nerves supplying the respiratory passages, so numerous and multiform are the exciting causes, and so various are the depots for the reception, and the channels for the transmission, of sensory impressions, that too much relief must not be expected from the removal of the turbinated tissues Moreover, an operation which will relieve one may not only benefit another, but may prove positively injurious I have known cauterizations of the back part of the lower turbinated body to cause the most distressing and alarming attacks of true asthma, which lasted for two or three months, and though the asthma apparently died out, it left a legacy that will probably make itself felt with every recurrence of a bronchial irritation I do not cite these facts to discourage those who might be benefitted by operative procedures,—and they may be many,—but because the truth touching all sides of this question should be known Another fact of importance to the patient is that after extirpation of the interior turbinated swellings, relapses may occur which will demand repeated operations But if the tissues are to be removed, the sooner it is done the better It should be borne in mind by the operator that it may be necessary to carry the destructive process into the vault of the pharynx, where granulations and adenoid vegetation may have become centres of irritation

The question will always arise In what class of patients may we expect the operation to prove curative or beneficial? It is obvious from the facts I have related, that we must confine this procedure to those cases in which there is a diseased condition of the mucous membrane of the nose or throat, or to those individuals in whom the paroxysms are provoked generally by irritants acting on these parts, or, I may mention a practical criterion by which to decide If a reliable preparation of cocaine, from four to ten per cent, will arrest a severe paroxysm when applied to the sensitive spots, an operation will probably be useful It might be supposed, on cursory examination of the subject, that this classification would include a vast majority of hay-fever subjects But a study of several hundred cases shows that in nearly one half the number attacks were occasioned, not by local irritants to the nose alone, such as dust, but by causes of quite a different nature Such patients may suffer at any and all seasons from various occult causes, and will probably prove refractory The other class consists of those

who inhale the materials which are provocative of their suffering Remove the material which irritates, or the tissue which is irritated, and we may confidently expect relief These are the people who suffer most in the summer months, when the grasses are ripening and the flowers blooming, and all the air is filled with the dust of the earth and the pollen of myriads of blossoming plants Let us hope that this class may supply medical literature with its most brilliant cures and its most grateful beneficiaries

719 W Adams Street

A NEW METHOD OF INTRA-PULMONARY MEDICATION, WITH REMARKS UPON ITS USE WITH PNEUMATIC TREATMENT

Read in the Section on Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY G W McCASKEY, A M, M D,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST FT WAYNE COLLEGE OF MEDICINE FELLOW OF THE AMERICAN ACADEMY OF MEDICINE ETC

There are few questions of higher importance in practical therapeutics than that of topical medication of the lungs In discussing this question we may start with the postulate that particles of matter can enter the alveoli with the inspired air, be deposited upon their walls, and taken thence into the circulating fluids of the lymph spaces and capillaries

If carbonaceous particles floating in the inspired air can enter the pulmonary tissue until it is colored black, then the possibility of similar medicinal agents behaving in like manner must be conceded These facts, first correctly interpreted by Bouckman in the lungs of miners in the Hartz mountains, have been abundantly confirmed by Lowe, Petrens, Traube, Zenker, Von Ins, and many other reliable observers Nor can it be argued that the processes of anthracosis are too slow to make their application to therapeutics practical or fair On the contrary, the absorption of these solid particles is remarkably rapid Ruppert, for instance, found soot in the bronchial glands of a rabbit after two hours' inhalation of smoke These particles of soot must have entered the lymph spaces, thickly set throughout the respiratory tract, and traveled the distance of the lymphatics to the bronchial glands in this comparatively short time To aid this so called absorption the irritation of the alveolar walls causes the exudation of large ameboid cells, which envelope these foreign particles in their protoplasmic bodies and wander back with them into the pulmonary structure as actually observed by Von Ins and Oertel To further show that these particles penetrate beyond the bronchial tubes, cinnabar has been found upon the alveolar walls a few hours after its inhalation If any doubt should still remain concerning absorption from the pulmonary surface, Ruppert's experiment of throwing India ink into the bronchial tubes, and finding the capillaries beautifully injected, and the urine perfectly black in twenty minutes, must be regarded as conclusive [1]

[1] For details and fuller discussion see Oertel s Respiratory Therapeutics.

The importance of absorption becomes apparent when we reflect that the energy of the therapeutic action depends in great measure upon the depth to which the agent penetrates in the inter cellular spaces of bronchial and alveolar walls

The real practical question as it stands to day is In what form and under what physical conditions can medicinal agents be most effectually introduced into and made to exert their influence upon the inter alveolar and deep bronchial structures?

Of the possible forms we may distinguish four, viz Dry powders, gases, pulverized fluids, and vapors

The use of powders by insufflation is practically limited to parts above the *rima glottidis* At any rate, however, their penetration beyond the tracheal bifurcation with sufficient uniformity to meet the requirements of topical medication is extremely improbable Their tendency to irregular distribution—to accumulate in some places, with none in others—makes their action correspondingly irregular For these reasons they can be dismissed from further discussion in this connection, although their actual penetration into the alveoli has been demonstrated

Gases are not open to the same objection, their physical conditions being precisely identical with those of the atmosphere The gases heretofore used for inhalation probably act more in a general way after absorption than by direct local action At least, the clinical results obtained are in accord with this view, and it may be assumed that the local therapeutic effect of the respirable gases is not sufficiently energetic to justify any very sanguine expectations in this direction

The construction, by Sales Giron, in 1858, of an apparatus for pulverizing fluids for purposes of inhalation opened a new era in inhalation therapeutics With the advent of the various spray producing appliances, the local medication of the larynx and trachea became easy and certain Whether pulverized fluids, *as such*, however, can penetrate the alveolar passages must be regarded as an open question The tendency of these fluid particles in transit is to coalesce and form larger particles or drops, which, by impact or gravity, soon adhere to the mucous lining, and this, long before they have reached the alveoli, or even the bronchioles The observations advanced to prove the penetration of these fluid particles, as such, into the alveoli are not at all conclusive In Zdekaur's case of fatal hæmoptysis (Oertel) the patient had inhaled just before death a spray of solution of perchloride of iron After death, Dr Hohn found an excess of iron throughout the pulmonary tissue But as there is normally only about one part of iron to two thousand of blood (Becquerel and Rodier), the introduction of an extremely small quantity would be sufficient to show an increase What did reach the alveoli was probably not spray but vapor Oertel seems to hold the same opinion, for he says "It is not improbable that what is already a steamy mist may, in the smaller bronchi and lungs, be converted into actual vapor"

If the purpose be simply to medicate the larynx, trachea and large bronchi, then the experiments of

Tavernier, Moura-Bauroullon, Gratiolet, Sommerbrodt and others definitely settle the question With moderately deep voluntary breathing it can be most effectively accomplished But I think it may be safely assumed that *pulverized fluids, as such, do not reach the alveolar spaces* To this it may be answered that so long as the medicine reaches its destination, its precise form is not of practical importance, however interesting it may be scientifically But such a position is entirely untenable, for the physical conditions and processes best adapted to each are dissimilar, and to use them indiscriminately is both unscientific and irrational

Vapors, unless intrinsically irritant, offer no essential obstacles in the way of inhalation Their physical conditions, while they retain the vapor state, are identical with those of a gas such as the atmosphere There are no particles to coalesce or be carried by impact against the angles of the respiratory channel They form an integral and homogeneous part of the atmosphere with which they are b'ended, and meet the physical conditions of respiration fully and completely But something more than mere contact of this mixture of vapor and air is desirable It should be condensed and deposited upon the pulmonary surface

But we are met here by adverse physical laws, for, as Mr Joseph Ketchum has pointed out, the increase in temperature of some twenty degrees which the inspired air undergoes (assuming the temperature of the room to be 70° F) will make it retain not only all the moisture which it could possibly be charged with before inspiration, but take up as much more from the respiratory lining, so that deposition is apparently impossible

Can these conditions be changed? Can the temperature of the air be lowered instead of raised after inspiration? If so, then vaporized medicines can be deposited through temperature influences alone where pulverized fluids can probably never penetrate without themselves being vaporized Inasmuch as the temperature of the respiratory lining can not be safely lowered, it is evident that the only practical method is to heat the vapor before inhalation The first question then is At how high a temperature can air, saturated with vapor, be inhaled? Dr Morell Mackenzie says[2] that it should never be inhaled above 160° F, and that it is practically useless below 130° F As to the higher limit I will simply say that I have repeatedly inhaled vapors at 170° F without the slightest discomfort I will assume 158° F as the safe limit, and base my calculations upon that

The hygrometric capacity of the air increases with its temperature in a geometric ratio In order to show the enormous increase of vapor capacity with rise of temperature, I have compiled the following table

Temperature	Per cent of Vapor	Aqueous Tension
32° F = 0° C	6	4 6 millimetres
50° F = 10° C	1 2	9 165 "
70° F = 21° C	2 4	18 50 "
95° F = 35° C	5 5	41 9 "
113° F = 45° C	9 4	71 5 millimetres
149° F = 65° C	24 4	186 "
158° F = 70° C	30 5	232 "

[2] Diseases Throat and Nose, Vol I, p 549

It will be seen that saturated air at 158° F is nearly one third vapor, and that if the relatively cold respiratory lining will cool it down to 113° F, it will be a little less than one tenth vapor In other words, it will deposit more than sixty nine per cent of the vapor which is contained at the moment of inspiration While the cooling process commences in the mouth, it continues as far as the inspiratory volume enters For the reasons already set forth, therefore, I believe that vapors should always be substituted for sprays, when the object is to medicate the pulmonary lining proper In order that the best results may be obtained, and the vapor administered on a scientific basis, there are several conditions which I conceive to be indispensable and which can only be fulfilled by some special form of apparatus The conditions are

1 The air and vapor to be inhaled must be confined in such a manner that it can be heated to any required degree, and the temperature steadily maintained and measured

2 The supply of respirable air must be practically unlimited

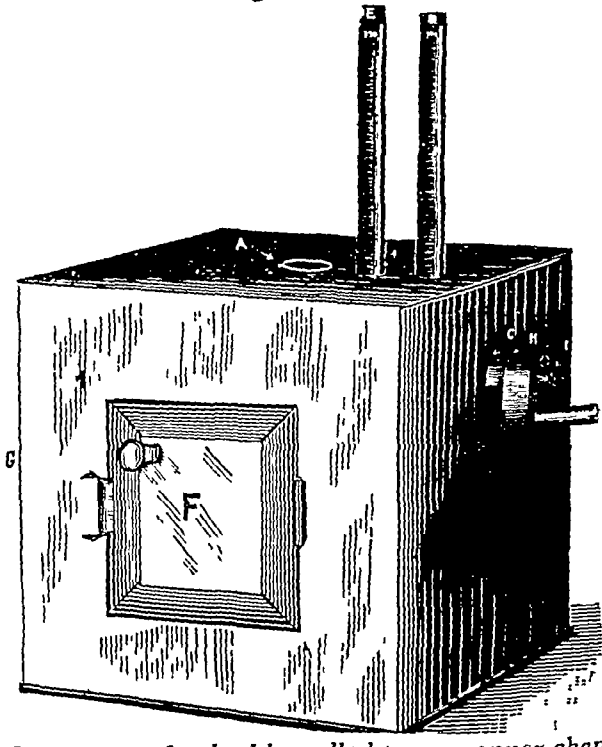
3 It must be impossible for the patient to expire into the compartment containing the medicated air

4 It must be so arranged that it can be saturated with the vapor of either volatile or non volatile agents, such as mercuric chloride

5 The respirations should be unembarrassed and continuous

6 There should be the least possible loss of heat by the vapor in its transit to the patient

The mechanism which I have finally adopted is shown in the following cut



It consists of a double walled tin or copper cham-

ber, having a capacity of one cubic foot, with an air space of one inch between the walls The external wall of the bottom has near its center a circular aperture some three inches in diameter, through which a Bunsen burner gas flame is allowed to play for the purpose of heating the contents of the chamber to the required temperature I have found it necessary to suspend a metallic diaphragm in the air space above this opening to prevent the flame from striking the inner wall, as the intense heat thus produced burns whatever comes in contact with the inner surface, producing pyroligneous acid and other offensive and irritating empyreumatic products With these precautions, the chamber will contain nothing but atmospheric air and the desired vapor In the outer wall of the cover is a smaller opening, A, which, acting as a flue, allows the mixture of heated air and gas from the Bunsen burner, after passing around the chamber in the air space between the walls, to escape without contaminating its contents This heated air circulating through the air space prevents the cooling of the outer stratum of the contents of the vapor chamber, with the resulting condensation At one side of this opening are two tubes passing through both walls, containing two carefully packed thermometers, D and E, with their registers projecting above Around the bulb of thermometer D is an envelope of thin muslin, which, being dipping into water, is kept wet by capillary attraction These thermometers serve the purpose of a hygrometer, indicating the degree of saturation with moisture, thermometer E also registering the actual temperature of the vapor

In front is a small door, F, six inches square, through which cups of water or medicine may be introduced, the temperature lowered if it becomes too high, or the interior cleansed

Another opening two inches in diameter, indicated by G, but not shown in the cut, furnishes fresh air, and allows a spray to be thrown into the chamber—the quickest and most satisfactory method of charging the air with vapor In using agents non volatile at ordinary temperatures, this is probably the only method by which they can be diffused in a definite strength in the vapor chamber Bichloride of mercury, for instance, can be uniformly diffused in this way so strong that the vapor is quite intolerable, and yet of a definite and easily calculated percentage

At any time before the saturation point has been reached the thermometer with the wick around it (bulb D) will stand from five to thirty degrees lower than the other The cooling of the bulb is produced, of course, by evaporation from the wick into an atmosphere which is capable of holding more moisture If, when thermometer D stands say at 120° F and E at 150° F—a combination which I have often seen—a dense spray is thrown in, the column in D will rapidly rise to the level of E, showing that saturation has occurred As long as these thermometers register the same temperature the air in the vaporizer is saturated with moisture for that particular temperature and pressure, and can not by any possibility contain more

Directly opposite the opening G is a tube C communicating with the interior of the vaporizer To this is attached the tubes for conveying the vapor to the patient First comes an oval compartment one by two inches and one inch long, which contains two valves, H and I, for controlling the currents of inspiration and expiration The valve H (not seen in the cut), is so adjusted as to close the passage *from* the patient toward the vaporizer, preventing the expired air from entering the latter, but opening freely in the opposite direction, allowing the passage of the medicated vapor The valve I is so arranged that it allows the escape of the expired air between the valve H and the patient's mouth This valve closes by its own weight at the end of expiration, so that the lungs can be filled only with the contents of the vaporizer, no air from the room being permitted to enter The force required to open these valves (they are both self closing) is very slight When used in connection with pneumatic treatment the valve H opens by differential pressure, and therefore offers no resistance The valve I must be forced open But the light weight, and the fact that it hangs only 22½° degrees from the perpendicular makes it of little importance

The oval compartment containing the valves can easily be taken apart after every treatment, washed with antiseptics and thoroughly flushed with water It is covered with a rubber band to prevent radiation of heat, while an ordinary rubber tube passes directly to the patient This tube and the oval compartment together have a capacity of seven cubic inches, which adds that much to the residual air, but I do not see how it can be materially reduced The temperature of the vapor in passing through these tubes to the patient will fall about ten degrees, so that the dry bulb thermometer should register about that many degrees higher than is desired for inhalation

With better facilities than were at my command the mechanical details of this apparatus could be materially improved But I am satisfied that it accomplishes the purposes for which it was intended, viz, the introduction into the lungs of air at a comparatively high but accurately measured temperature, saturated beyond question with medicated vapor of definite composition, using either volatile or non volatile agents, in order that the relatively cool mucous lining may lower its temperature and cause deposit of its suspended moisture The precise physical condition of non volatile agents prepared in this manner is an interesting question Such agents as mercuric chloride, sulphate of zinc, etc, can only be volatilized from the dry powder at a very high temperature The fumes or sublimates thus produced can only be diffused through the air in uncertain proportions If placed in solution and boiled the resulting vapor will of course contain nothing but water But if made in solution of any desired strength and sprayed into a heated atmosphere the particles of finely divided fluid instantly vaporize, and the vapor holds in solution the same percentage of medicine as the water from which it was made Knowing the capacity of the air for vapor at any given temperature and pressure, and having the com-

parison of the wet and dry bulb thermometers to indicate the degree of saturation, we can easily calculate the exact quantity of medicine in each cubic inch of air inspired If we could determine the reduction of temperature and increase of pressure which takes place in the respiratory tract we would possess all the elements for an accurate computation of the amount of medicine deposited in the lungs It remains for future investigation to complete these data if it be possible, but in the meantime, I believe that our knowledge of physical and physiological laws warrants the belief that in this direction lies the highest measure of success in typical medication of the lungs

The idea of combining topical medication with pneumatic treatment is not of recent date It is only necessary, however, to refer to the older methods to show their inefficiency Crow caused compressed air to pass through one or two Wolff's bottles filled with hot aqueous solution of sal ammoniac before inhalation As sal-ammoniac sublimes only with dry heat it is needless to say that his patients only received hot aqueous vapor, with a few particles of solution mechanically carried over (Oertel) The quantity introduced must have been entirely problematical and accidental This method with volatile agents was followed by Waldenburg, Cube, and Domansky Dr Crabbe's method was to fill the Waldenburg condenser with air charged with vapor and then compress it A large proportion was lost in the water by compression and absorption, and only a small and indefinite quantity reached the lungs The results were so unsatisfactory and the methods so unscientific that Oertel declared the number of medicines which could be used in this way almost limited to a few ethereal oils, and advised abandonment of further efforts to combine topical medication and pneumatic treatment The persistent efforts which these pioneer investigators made for the simultaneous accomplishment of these two objects clearly shows their opinion of its desirability

There are various anatomical and physiological reasons why medication of the alveolar walls can better be accomplished during increased pulmonary pressure The increased air space present is produced almost entirely by the distension of the elastic alveolar walls This increases the area of absorption, and not only so, but it renders medication possible in certain areas, such as the apices, or partially collapsed lobules, where expansion is ordinarily imperfect The increase of the tidal volume of air which spirometric tests have demonstrated, increases the movement of the lung structure, and quickens the flow of lymph in the spaces having their origin in the alveolar walls The direction of this flow is of course *from* the alveolar septa, and to accelerate it is to promote absorption Thus the conditions of increased intra-pulmonary pressure are the best possible for topical medication of the alveolar walls, besides which we get the combined results of the two processes

With the older pneumatic apparatus simultaneous topical medication was manifestly impossible With the Ketchum Cabinet, however, the conditions are under complete control, and we can distend the alveolar passages to any allowable extent, and introduce medicinal agents with the same facility as before expansion I believe that this combination of mechanical and medicinal therapeutics offers the most favorable outlook for the treatment of that class of pulmonary diseases in which increased intra-pulmonary pressure and topical medication is indicated. This includes more particularly bronchitis and phthisis, while in the more purely mechanical treatment of emphysema, unresolved pneumonia, and pleuritic exudations, it will occasionally be found useful for the treatment of concomitant conditions

In conclusion, it affords me pleasure to acknowledge my indebtedness to Dr H F Williams, of Brooklyn, and Mr Joseph Ketchum, of New York, for valuable suggestions

GLANDERS IN THE HUMAN SUBJECT—WITH A CASE

Read before the Section of Practice of Medicine, Materia Medica and Physiology, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

BY C N COOPER, M D,
OF CLEVELAND, TENN

Glanders is essentially an equine disease, and found among horses, asses and mules the world over The names *equinia* and *farcy* are also given to this malady Aristotle described a disease identical with this, among the horses of his time Its prevalence in any country is said to increase from 50 to 100 per cent during and after a war As to its spontaneity veterinarians do not agree Some aver that every case is to be traced to some other case, as in measles or small-pox in man, others deny this, claiming that, under favoring circumstances, it originates *de novo* All agree that there is a glanders bacillus, but do not agree as to whether it is the cause or concomitant of the disease

It is not in the province of this paper to discuss this point at length, but I cannot let it pass without calling attention to the fact that horses that have been apparently in perfect health all their lives have been known to become glanderous when crowded together on shipboard upon long voyages This is often the case when, on account of storms, the hatches are closed much of the time, so that the air becomes stifling and impure Horses subjected to great privation and those kept in damp, ill ventilated stables, seem sometimes to develop this disease spontaneously It does not seem to me probable that the bacilli of glanders could exist, latent, in the animal for an indefinite period, waiting for favoring circumstances to present themselves for their development The virus exists in all the fluids of the affected animal, even the semen It is an important fact, to be remembered, that a glandered horse may be fat and sleek, and, because of his healthful appearance, become a ready source of contamination to other horses or to man All are agreed that this disease

never originates in the human race I am confident, though this is a disputed point, that its virus is a fixed poison like that of vaccinia or syphilis, and cannot be conveyed except by some form of inoculation From my own experience and observation, as well as from the meagre literature there is upon this subject, I conclude that there must be some solution of continuity where the virus finds ingress This may be upon the skin, or upon some mucous membrane, as the mouth, nose, air passages, or possibly the vagina

Very little has been written upon this topic Two centuries ago Helmont ventured the suggestion that glanders might have been the original source of syphilis Later, Ricord revived the idea, but Virchow concludes that it is impossible So far as I can find, the first case reported was by Lorin, in 1812 The next was by Muscroft, of Edinburgh, in 1821 Copeland, of London, also reported a case about the same time In 1828 Prof Coleman wrote a paper on the subject, and not long after Rayer gathered all that had been written, up to that time, into an elaborate paper published in vol vi of "Mémoires de l'Academie Royale de Médicine " Ziemssen's work contains a lengthy article on the subject, as also Pepper's "System of Medicine " In Quain's Medical Dictionary a fair mention is made of this disease, yet I imagine that the busy practitioner who is called to a suspected case may read all that is written upon the subject, then turn away feeling that he is thrown upon his own resources for both diagnosis and treatment, and however well read he may be, he may be pardoned for failing in his diagnosis when called to his first case, acute, subacute, or chronic

The incubation of glanders occupies from three to five days The attack is ushered in by a chill of greater or less severity, acute pain like that of rheumatism, yet without local inflammation, and an indescribable *feeling of languor* The temperature soon becomes high, the pulse quick, weak, and unsteady, the tongue heavily coated, soon becoming dry and brown There is constipation, and scanty urine The teeth and lips early take on sordes The pain continues, now here, now there, but is prone to be cephalalgic, and often intense Nodules appear promiscuously about the face and body, and often break down into bullæ Deep abscesses form, involving both cellular and muscular tissue, these are painful, and mature very slowly, discharging, when opened, a thin, dirty, sanious pus At the point where the abscess is opened, a deep ulcer soon forms, which seems to be a sort of sloughing of the integument and immediately underlying tissue These heal very slowly, if at all A papular rash also appears here and there upon the body, but seems to be insignificant The mucous membranes early become dry, then form ulcerated spots, from which a fetid muco pus discharges The integument becomes earthy and cadaverous, and the whole body exhales an offensive odor Day by day the trouble advances, baffling all efforts to check it, and the patient usually dies, in from one to three weeks, in a loathsome condition

If the attack is subacute, the duration is longer, but is only a prolonging of the agony, until death comes to the rescue Some cases, however, linger for months, or even years, in their misery, and finally die from exhaustion, unless, indeed, the patient becomes wearied out with what seems to be a hopeless contest, and ends his suffering by suicide A few cases of recovery, however, have been reported After detailing a case which was under my care for nearly two years, I will consider somewhat the differential diagnosis between this disease and several others with which it may be most easily confounded.

Mrs Lorenson, native of Germany, a widow, æt. 23, came under my care on June 24, 1884, with the following history In September, 1883, her husband, living near Elgin, Ill , bought a fine looking horse, said to be suffering with an ordinary distemper, for which he at once began to treat him Very soon after, Mr L was taken sick He had a well marked chill, severe pain in different parts of his body, and extreme languor His physician diagnosticated some form of blood poisoning, but could not determine its exact nature He was seen by several competent physicians, who were all in doubt about the case, until he told them of the horse he had been treating An examination of the horse led to the belief that its trouble was glanders Dr Paaren, then State veterinarian of Illinois, was called, and pronounced it a true case of glanders There was now no doubt as to the nature of the trouble Nodules formed here and there, and broke down into bullæ Deep seated, painful abscesses also appeared, and failed to heal After about three weeks of suffering, he died in a most loathsome condition, but not until his wife had become contaminated Her attack was similar to his, but less severe, and by prompt, energetic treatment she was so far restored as to be able to perform some domestic duties, until the following June, when she suffered a relapse and was brought to the "Poor Farm " She was placed in a small isolated house, to be cared for by a "sister" from a convent in Chicago I now copy from my notes, taken during the progress of the case

Mrs L is suffering severely from a hemicrania She has a purulent vaginal discharge, a small ulcer on the right thigh, nearly healed, and a large one in *the roof of the mouth, with angry, ragged edges*, and a patch of denuded bone about 5 lines in diameter just back of the right canine tooth Small patches of ulceration extend into and down the throat as far as can be seen Her face is swollen, and her eyes expressionless The tongue is heavily coated and the skin is of a dirty gray color Her pulse is 110, very weak and unsteady She has no appetite, is much emaciated, and a sickly odor emanates from the body The urine is scant and thick, and bowels constipated She has been informed that she can live but a short time, and cares not how short the time may be Gave a brisk cathartic, to be followed by syr iod of iron in full doses every four hours, to be alternated with a capsule of quin sul , ac salicyl , and morph sul She is to have all the milk, beef and eggs she can take All ulcers are to be thoroughly cleansed three times a day, and dusted with a powder of soda, sulphur and iodoform, equal parts All her underclothing, and everything about her at

all soiled, are to be burned, and strict attention given to cleanliness, disinfection and ventilation Frequent alkaline baths and changes of clothing ordered, and every soiled cloth or garment is to be burned as soon as removed

July 1 Patient suffers less, and is less despondent, takes milk and eggs fairly well Substituted pot iod, ammon mur, and hydrarg bichlor for the iodide of iron, but continue the capsules four times a day

July 4 The iodide mixture is not well borne, give citrate of iron and quinine instead, and the capsules are to be used only for relief of pain, which is not very troublesome A swelling under the left eye threatens an abscess, and both eyes are red and swollen Thinking the iodoform may be the cause of some of this disturbance, this is to be used only on the leg ulcer, and the mouth ulcer is to be treated with a saturated solution of boracic acid in glycerine

July 10 The eye trouble has disappeared, except the abscess forming under the left eye, which is now being poulticed The vaginal discharge is much diminished, the appetite is good, and she is quite cheerful Treatment continued

July 12 Dr Hard, of Aurora, visited the patient with me to day, but declined to give any advice, except to wash ulcers in a sulphurous acid solution A thin piece of bone, as large as the finger nail, has exfoliated from the roof of the mouth, and the ulcer is reduced to the size of a quarter of a dollar, while those of back part of the mouth and throat have disappeared, leaving the membrane thickened and granulated, The fetor of the body is gone, but the breath is still offensive She is gaining in flesh, and the skin has improved in color The leg ulcer gives no further trouble She suffers considerable pain in her back, indicating a return of her menses, which have been absent since February

July 16 The abscess under left eye has matured and been lanced, another one appears to be forming under the right eye There are numerous small, hard nodules about the face, and a deep, painful swelling in the calf of the left leg An abscess has discharged spontaneously in the right labium, but gives very little trouble Poultices are ordered for the leg, and tinct iodine for the swelling and the nodules upon the face, and tr of iron and cod liver oil internally

August 1 The abscess under right eye is discharging quite freely The nodules are all gone, and the leg is less painful, but an abscess is unavoidable The ulcer in the mouth is slowly healing, but an ugly one under the upper lip is very obstinate, probably because not well cleansed I have ordered it syringed three times a day, and packed with absorbent cotton wet with boracic acid and glycerine Her appetite remains good, and she goes about the yard, spending much of the time out of doors, when the weather permits

August 15 The mouth ulcer has healed, leaving the root of the canine tooth exposed almost to its point That under the lip is improving The abscess on the leg is now discharging, and giving very little trouble A small ulcer marks the spot of the abscess under the left eye, and a large one that under the right eye, where the integument and underlying tissue sloughed, leaving an excavation 2½ inches long by 1 inch wide, extending to the periosteum, which seems healthy The vaginal discharge has entirely ceased, but she suffers a good deal of pain in her back, for which a chloroform liniment is ordered She is fleshy, eats very heartily, and is very hopeful

September 1 The liniment affords but temporary relief to the pain in the back, and she is ordered to take a hip bath before retiring The face ulcer refuses to heal, and I have cauterized it thoroughly with solid nitrate of silver She is now taking cit iron and quinine in maltine

September 5 Was called in haste to day to see my patient, and found her suffering intense pain all over her She had had a severe chill, and now the face was very red and swollen, the pulse 120, hard and cordy, and the temperature 104° I found that she did not take the hip bath until this morning, after which she went directly out of doors into a chilly air, and sat down for a half hour, when the chill occurred I gave her liberal doses of quinine and aconite

September 6 Temperature normal, pulse 90 and weak, the face still swollen and erysipelatous The iron and quinine in maltine is resumed

September 15 Face ulcer looks as though it would enter the eye, in spite of iodoform and argent nitras In all other respects she is doing well again The ulcer which formed at the opening of the leg abscess has healed For one week she is to take Fowler's solution, and the iodides of lime and soda in sarsaparilla, then a tonic of iron, quinine, and strychnia

October 1 The face ulcer is at a standstill The menses have appeared, and she says she feels well She walks a mile without tiring, and spends all the pleasant hours in the open air

November 1 Patient is doing well in every way, except that there is no improvement in the ulcer, which I am cauterizing every three or four days

November 10 The ulcer has burrowed under the lid and entered the eye, lighting up a most fearful inflammation The injected cornea is seen in a depression of the thickened conjunctiva, which has the appearance of a piece of raw beef The aqueous humor is cloudy, and there is simply a perception of light The pain, of course, is intense, and she utterly refuses food Hot fomentations are to be constantly applied to the eye, and sufficient anodynes given to relieve pain

November 15 Patient is emaciating perceptibly She takes no food except a little milk There is no change in the appearance of the eye, but she gets a little more sleep, by the use of the anodynes The right side of the face is paralyzed The extremity of the infra orbital nerve is doubtless destroyed The appearance of the face is brutish, and she is greatly depressed mentally It is scarcely possible to properly cleanse the eye

December 1 She has lost all the flesh she had gained and takes no food but milk with lime water No medicine is retained except tablets of morphine and atropia A preparation of morphine and atro-

pia in a saturated solution of borax in rose water is applied freely to the eye She now consents to enucleation, but the operation would be unwarranted in her condition The pulse is 140, small and very irregular, and death seems inevitable and imminent

December 5 Patient has rallied, pulse 100 and more regular, and the intensity of the conjunctivitis has somewhat subsided She takes more milk and a little broth, but no medicine except the tablets

December 15 Considerable improvement She takes one quart of milk and one or two eggs every day, besides occasionally a little broth or gruel Her menses have again appeared The cornea and aqueous humor are clearing slightly, and there is a corresponding improvement in the sight There is much less pain and swelling about the eye Local treatment continued, and tonics resumed

January 1, 1885 Eye trouble is gradually subsiding, and a diet of milk, eggs, meat and coffee is relished Urine scant and thick Right knee painful, without swelling or redness Chloroform liniment ordered for the knee, which is to be wrapped in hot cotton batting Pot brom , acet rad , and spts æther nitr in lemon syrup internally

February 1 Destructive process in the eye has reached its height The conjunctiva is so far destroyed that the eye seems to have no attachment except the muscles, which are visible, and the vessels and nerves, yet there are slight indications of repair Ordered a fine powder of boracic acid and iodoform to be dusted into the eye night and morning, after thorough cleansing, and the eye to be kept covered The kidneys are more active, and menstruation has again occurred, delayed but one week There is a discharge of watery pus from the right ear, which is to be kept cleansed and the iodoform powder applied as to the eye Pain continues in the knee, where an abscess is forming The flexor tendons are quite contracted Internal treatment, syr iod of iron, and quinine

February 15 Blister applied to knee, which is still quite painful, with no progress toward suppuration The ear gives no further trouble Iodoform powder discontinued, and morphine and atropia solution freely applied to the eye She eats and sleeps well and is taking on flesh again

March 1 Gradual improvement in all respects except the knee, which remains the same in appearance, but is less painful All sensations normal, and she would be about the house and yard but for the knee She can see the bars in the window sash across the room with the affected eye As an experiment am now giving her McDade's prescription instead of the tonic The eye wash is continued Drs Robbins and Milbacher, of Aurora, visited the patient with me, and advised enucleation if acute symptoms should recur so as to threaten the well eye

March 10 Fluctuation seemed evident in the affected knee, but the exploring needle shows only blood Blister renewed

March 20 Patient weakens under McDade's prescription, and I have added iron and quinine for internal treatment Poultices are resumed on knee

April 1 Abscess lanced, discharging about 3 oz of thin sanious pus Poultices continued The small ulcer under left eye is healed, and the one under right eye is nearly healed, there being only a deep spot at the right inner angle of the eye, where the lid lost its continuity with the nose There is marked improvement in her general appearance

April 15 A deep ulcer marks the spot where the knee abscess was opened, but there is no pain The knee is flexed to nearly a right angle There is a suspicious puffiness about the left ankle, with a good deal of pain After painting the whole ankle with tinct iodine I have applied a thick layer of cotton batting, and over this a rubber bandage, from the toes, as tight as she can bear This is to be repeated every other day

May 1 Right knee has healed, but is very tender and quite swollen It is dressed simply with cotton batting, held in place by a firm roller bandage Left ankle and foot are somewhat painful and considerably swollen Cotton and bandages continued She failed to menstruate in April, and feels heavy dragging pains in her back and hips, otherwise she feels well, and is gaining in flesh

May 15 Severe pain in the left shoulder, without swelling or redness No pain in foot or ankle Chloroform liniment and hot cotton applied to shoulder, and sod iod , sod brom , and salicyl internally, alternating with iron and strychnia Eye trouble improves slowly

June 1 Shoulder somewhat better, treatment continued Under the influence of oil, rubbing and stretching, the flexion of the knee is yielding, and patient gets about the room by the aid of a chair Deep ulcer at the inner angle of the eye is slowly filling I apply solid argent nitr about once a week and the eye wash night and morning

June 15 Pain has passed into the right shoulder, leaving the left perfectly free, but it is not very severe Patient is cheerful and hopeful

July 1 Pain in shoulder is not constant, but when absent there, is felt in right thigh, but not so severe as to prevent her getting out of doors with the help of crutches Menses appeared in May and June without pain She can distinguish large letters with the affected eye, and knits or sews most of the time Is now taking syr iod of iron in an elixir of bark and iron

August 1 Another abscess has appeared and matured rapidly below the right knee, two inches from the site of the former It is quite superficial, and but slightly painful I attribute this one largely to excessive eating with too little exercise She is very fleshy Am varying treatment somewhat, but adhering to alteratives and tonics

September 1 A small ulcer formed when the last abscess was opened, but filled and healed very quickly For two weeks there has been some ulceration in the throat, which I have thoroughly cauterized every three or four days, while she has applied a powder of sulphur and soda t i d Powder is to be continued Her condition is very hopeful, though the blood is still lacking in red corpuscles

January 1, 1886 The case has progressed well, though slowly, since last note Menses seem fairly

reestablished, not having missed since April Will advise that she be moved to the Poor House, as a matter of economy to the county and of comfort to the patient I have strong hope that in the spring she may go out into the world again, and support herself

February 1 Patient has been removed to Poor House Is suffering from a "cold" with some hoarseness and sore throat The mucous membrane is rough and thickened I cauterize it occasionally, and she applies the sulphur and soda powder Otherwise she is doing well

March 1 I took patient to Chicago to be operated upon for the ectropion, which, with the drooping of the angle of the mouth is all that prevents her presenting a picture of health The wound is healing well, but there will be but little improvement in her deformity, owing, doubtless, to the paralysis of the cheek muscles

April 28 No appearance of a return of the disease, and I feel quite confident that, if she follows directions, she will remain free from it For some weeks she has been taking a mixture containing tincture of iron and ammon muriate Upon her promise to continue this every alternate week for at least three months, I have consented to her leaving the "House," and she has gone to day to do housework upon a farm I will endeavor to ascertain her condition from time to time, hoping, however, that she is at last free from her malady

As to the differential diagnosis and treatment, something remains to be said In the onset of the disease I think we may exclude rheumatism, for though the pain is similar, we would not expect so severe an attack of rheumatism without inflammation of some of the joints We may exclude idiopathic neuralgia, for the constitutional disturbance is too great A severe attack of erysipelas may be suspected, but in erysipelas we do not find so much pain and depression, and the headache is general, and of a dull, perhaps throbbing character, while that of glanders is decidedly neuralgic The initial pain, fever, and languor of diphtheria often precede the throat lesion, and are not unlike those of glanders, but if no membrane appears within 24 or 36 hours we may be warranted in excluding diphtheria In typhoid fever we usually have premonitory symptoms Then, too, the pain is mostly confined to the back and head In glanders the attack is abrupt, and the pain general. One may well be pardoned for thinking he has a case of acute blood-poisoning, in which he is not able to trace the source, for glanders is emphatically a hæmotoxic affection, and both victim and physician may be entirely unsuspecting, until, perhaps, some chance remark leads to an investigation which reveals the history of glanders in connection with the case

Between chronic glanders and secondary or tertiary syphilis there is a similarity, yet with care I think there need be no mistake A marked characteristic in glanders is great loss of red blood corpuscles, even though the patient is well nourished otherwise Such is not the case in syphilis The persistent periosteal tenderness of chronic syphilis is not found in glanders, nor the copper-colored erythematous patches, syphilitic ulcers tend to spread and to deepen, and have a special affinity for the periostum and bone Those of glanders neither spread nor burrow, except occasionally in loose areolar tissue, and it is very rare for the periosteum or the bone to be implicated The body fætor of glanderous patients is peculiar, almost cadaverous, and not like that of syphilis The discharges from glanderous abscesses are peculiarly ichorous, not unlike the fluid which drains from extensive gangrene With these distinctive points in view, the careful observer should be able to distinguish between these affections

I am of the opinion that the virus is somewhat weakened by passing through the human system, and that the disease contracted from man is more likely to be subacute, and more amenable to treatment than when contracted directly from the horse

As to treatment, very little instruction is given in the books Gross says "Bleeding, both local and general, purgatives, tonics and stimulants have proved alike useless" He advises irrigation and cauterization of the wound, or excise it This is certainly sound advice if we can see the patient before the virus has entered the system, but, unfortunately, this is seldom the case When bitten by a venomous or rabid animal, the victim knows at once that he is injured, and seeks instant relief The victim of glanders is unsuspecting, and almost invariably ignorant of the fact that he has been inoculated, until the incubative stage is complete, when it is too late A few hours even will suffice to fill the system with the poison, which we must endeavor to antidote or eliminate if we think to benefit the patient In the nature of the case all depletion must be avoided, and the system sustained by every possible means The treatment must be prompt and heroic After a careful study of the subject from all the sources at my command, I conclude that quinine in large doses, often repeated, so as to bring on cinchonism as quickly as possible, supplemented with tincture of iron, freely administered, either with the quinine or alternating with it, will give the best results that we can look for in this terrible disease At the same time we must nourish the patient in every possible way If in this way, or indeed in any way, we succeed in changing an acute into a subacute attack, we shall have increased the chances of recovery tenfold I have a strong hope that when we shall have learned more of the true nature of this malady we shall be able to treat it with a reasonable degree of success

I am glad to be able to add the information, just received by letter, that Mrs Lorenson is strong and vigorous, and earning good wages as a housemaid

Cleveland, Tenn , October 1, 1886

DISCUSSION

DR SMITH, of Iowa, had had a patient similarly affected from a glanderous horse

DR H W. HITZERAT, of Pennsylvania, had had a case like Dr Cooper's first Patient had neuralgic pains, with a fatal result in nineteen days

Dr Staples, of Minnesota, had a case which occurred in Readville last fall The patient died after a short illness, with symptoms similar to those mentioned by Dr Cooper

MEDICAL PROGRESS.

Cannabis Indica in Diarrhœa.—Dr Frederick F Bond and Mr B E Edwards, of Rastrick, say Dr S J Rennie, of Cawnpore, in the *Indian Medical Gazette*, for December, 1886, calls attention to the value of cannabis indica in the treatment of dysentery We wish to draw attention to its value in a similar condition, namely diarrhœa, especially in the type known as summer diarrhœa or English cholera. Attention was drawn to it in this connection by Dr Turner, in the *Lancet* (vol ii, 1886, p 536) He says "In ordinary diarrhœa (referring to summer diarrhœa presumably) the formula

℞.	Tincture cannabis indicæ	♏x.
	Spiritus chloroformi	♏x
	Tincture kino	ʒj
	Aquam menthæ piperitæ ad	ʒj

in a modified dose, will be found very serviceable Being connected with a dispensary where thirty to forty cases of diarrhœa presented themselves daily for treatment during the months of August and September, and where a great variety of remedies were tried, so great was the superiority of Indian hemp above the others, that the patients themselves got to know it, and invariably asked for the green medicine "

We have been in the habit of prescribing it in nearly all forms of diarrhœa with marked benefit, combined with medium doses of morphine In summer diarrhœa the effects are very striking There is no necessity to record cases, they are all very much alike, the great depression, the frequent watery stools, the vomiting, and the cramp like pains are very quickly relieved, the appetite speedily returns, and by the following or third day the cases are practically well, except for some weakness and debility The formula we generally use for an ordinary adult is

℞	Tincture cannabis indicæ	♏x
	Liquoris morphinæ	♏v vel ♏x
	Spiritus ammoniæ aromatici	♏xx
	Spiritus chloroformi	♏xx
	Aquam ad	ʒj

To be repeated every one, two, or three hours according to circumstances Directions *No food for several hours, but a little brandy and water* We have not seen one case run on to a fatal issue under this treatment

It appears to act by increasing the astringent and anodyne properties of the morphine (the dose of morphine would have very little effect alone), by its stimulant effect on the nervous system, improving the tone, and by improving the appetite, thus enabling the system to quickly overcome the marked depression and exhaustion Most remedies in this disease rather retard the return of the digestive function, but from our experience Indian hemp markedly accelerates it Indian hemp seems, also, frequently to counteract the bilious action of morphine, as well as the loss of appetite, and allows it to be given where it otherwise would not be tolerated

In other forms of gastro intestinal disturbance it is also valuable, probably for the same reasons It was of marked use in a case of subacute gastro enteritis, which had existed for a few weeks before it came under our care, in a girl aged 13 years, showing the following symptoms marked anæmia, which had gradually come on after the other symptoms, constant pain over the abdomen, especially in the epigastric region, increased on pressure and after food, tongue covered with yellowish white fur, loss of appetite, vomiting at variable times after food of partly digested material, diarrhœa, six or eight stools in the day, which were watery and green, containing partly digested food material, some rise in temperature—a little over 100° F She was first treated with bismuth, then with effervescing mixtures, with no benefit, then with the cannabis mixture (modified to suit her age), and the symptoms very quickly subsided, the vomiting and diarrhœa were checked, the pain ceased, and the appetite returned By the end of the week all the symptoms had disappeared except the anæmia, which persisted for a short time longer

In cases of tuberculous diarrhœa we have not seen much benefit, beyond a slight relief of symptoms for a short time, though we have not had sufficient experience in this type, nor in the excessive diarrhœa in typhoid fever.—*The Practitioner*, July, 1887

Naphthalin in Intestinal Catarrhs and Dysentery.—Following the recommendation of Professor Rossbach, Dr N M Doigopoloff, of Kursk, administered (*Proceedings of the Medical Conference at the Kursk Zemsky Hospital*, January–June, 1886, page 137), naphthalin in about 140 cases of acute and chronic dysentery and acute and chronic catarrh of the large bowel in children and adults The drug was given in the dose, varying from 1 to 5 grains, five times a day, either alone, or simultaneously with an emulsion containing castor oil and opium Only in two cases naphthalin caused vomiting, and was discontinued, and only in four it remained inactive In the remaining case (as far as their subsequent course was known to the author) the remedy gave excellent results, and that even in patients who had been previously vainly treated by various ordinary means Already, after a few first days of the treatment, diarrhœa subsided to rapidly cease altogether, tenesmus diminished stools lost their offensive odor, etc The author details the case of a boy, aged 9, with chronic dysentery of two years' standing, where recovery ensued from the use of 60 1 grain pills (taken four or five times a day) In another child, aged 2, with dysentery of eighteen months' duration, the same result was obtained from giving 1 grain doses three times daily for twenty days In acute cases diarrhœa sometimes ceased after a three days' treatment by naphthalin Dr V I Doljenkoff, of Kursk, also adduces two cases of follicular enteritis where diarrhœa ceased after 3 and

2 5-grain doses of the drug It reappeared, however, after discontinuing naphthalin The naphthalin treatment of diarrhœa proved successful also in the hands of Drs Kurkovsky, Falkenberg, Novikoff and Smatkoff, while Drs Schwarz and Karst speak of it very unfavorably —*London Medical Record*, May 16, 1887

HYSTERECTOMY IN CANCER OF THE UTERUS —DR SAUVE, of Paris (*Gaz de Gynécologie*, Vol II, No 23), after having reviewed a large number of reports from other countries, summarizes the subject as follows

1 Hysterectomy in cancer of the uterus does not deserve the disfavor with which it is regarded by the French It is capable of affording the patient a long period of ease In cases where the disease returns after operation it is attended with less pain

2 Hysterectomy is indicated

a When a removal of a portion of the uterus has failed to give satisfactory results

b When such a partial operation is manifestly impossible or insufficient

c When cachexia is too far advanced and the parametrium is still healthy

d It is favorably contraindicated when there is marked cachexia adhesions with neighboring organs or implication of remote organs As a corollary to this proposition it is necessary before operating to assure one's self of the condition of the parametrium by an examination conducted with the aid of anæsthesia

e The operation is not more difficult than the principal abdominal operations The statistics of the operation are constantly improving

f The method of election is colpo hysterectomy Laparo-hysterectomy should be reserved for cases where the body of the uterus is too large to pass through the vaginal wound, it is an unsatisfactory operation under ordinary circumstances

The most vigorous antisepsis is essential to success Iodoform, and particularly iodoform gauze, is much more valuable than carbolized dressings As a rule it is best to apply sutures without drainage

TREATMENT OF FRACTURES OF THE FEMUR —DR THIRIAR, in an interesting clinical lecture to the Brussels medical students on the treatment of fractures of the thigh, pointed out the advantages of the telescope apparatus proposed and described by Professor Derobaix some seven years ago This consists, firstly, of a starch bandage reaching from above the knee to the foot, provided with a stirrup and a cord, which passes over a pulley, and has a weight attached to the end in order to keep up constant extension, and, secondly, of a femoro pelvic starch bandage, which is applied two or three days after the first bandage, the upper part of which it covers so that the one may slide within the other in telescope fashion When dry, the femoral portion is slit up It can thus be opened and the seat of the fracture inspected at pleasure, and if necessary, manipulated by the hands, while an assistant makes any required degree of traction on the leg Afterwards it can be tightened up by straps and buckles with which it is provided, and the limb is then absolutely protected against all lateral or see saw movements, while the patient can be moved as much as is necessary for purposes of cleanliness without endangering the rigidity of the fractured limb By this means Dr Thiriar believes better results can be obtained than by any other apparatus, and he publishes a list of thirty cases, in all but two of which there was either no shortening or so little that it did not amount to a quarter of an inch In one of the two unsuccessful cases the patient was excessively unruly, and in the other no amount of manipulation appeared to reduce the deformity when first seen —*The Lancet*, July 2, 1887

BINIODIDE OF MERCURY IN SCARLET FEVER —DR CLEMENT DUKES says I have now given the biniodide in several cases of scarlet fever—with this result, that it not only arrests the fever, but it prevents the desquamation of the skin, or arrests it to such an extent that only a slight scurfiness of the skin of the hands and feet arises If such be found to be invariably the case, will the bacilli of scarlet fever be found in the skin at all, and, if not, will not the infectious period of scarlet fever be thereby reduced to a few days only, and will not the sequelæ of scarlet fever be absolutely prevented?

The biniodide can be administered in the form of a pill, or as a mixture of the liq hyd perchloridi c pot iodid The only drawback to its use which I have at present found is that if it be given before the diagnosis is absolutely certain, the physician will be apt to think, when he finds no desquamation taking place at the usual time, that the case was not one of scarlet fever The drug prevents the desquamation of the epithelium of the tongue, as well as of the skin, and the throat rapidly heals under its use

The benefit to be derived from the use of biniodide is far-reaching if it is reliable in all cases, for it not only prevents the desquamation of the skin, and thereby probably prevents the major part of the infectious nature of scarlet fever, but it will probably also be found that it obviates the necessity of keeping patients in bed for three weeks, which is the only safe rule hitherto, and isolated for five or six weeks, and will prevent the occurrence of the much dreaded sequelæ —*British Medical Journal*, July 9, 1887

DIAGNOSIS OF BEGINNING CARCINOMA OF THE CERVIX —Admitting the difficulties in the way of an accurate diagnosis without the aid of the microscope, STRATZ holds that such a diagnosis is not impossible He gives the following as the principal diagnostic points

1 The diseased part is in sharp contrast to the surrounding healthy tissue

2 A difference in level between the diseased and the sound parts can always be seen

3 The carcinomatous spots are always characterized by a light yellow color

4 The malignant portions exhibit small, yellowish white, shining elevations, at least in some parts —*Centralblatt fur Gynak*, No 19, 1887

THE REPORT ON ANTI-RABIC INOCULATION

Almost simultaneously with the report of the British Commission of Inquiry into M Pasteur's Treatment of Hydrophobia, which has just appeared, comes a book entitled "M Pasteur et la Rage," by Dr Lutaud, editor of the *Journal de Medecine de Paris,* and as if to make the subject more complete up to date, the *British Medical Journal* of July 2 contains a letter from M Pasteur to the Imperial Royal Society of Vienna, concerning the recent publication of Dr von Frisch on Hydrophobia The British Commission consisted, it will be remembered, of Sir James Paget, Sir Joseph Lister, Sir Henry Roscoe, M P, Dr Richard Quain, Dr Lauder Brunton, Professor Burdon Sanderson, Dr George Fleming, Principal Veterinary Surgeon of the British Army, and Mr Victor Horsley, Professor Superintendent of the Brown Institution

There is a good deal of difference between the report of the Commission and Dr Lutaud's book The one is the result of calm, deliberate, scientific work, the conclusions being based on *facts,* many of them being acquired by patient experimentation Certain members of the Commission visited Pasteur's laboratory and investigated a series of his cases, and the report is founded upon their observations, upon the opinions and statistics published by M Pasteur, and upon experiments made for the Commission by Mr Victor Horsley Two rabbits inoculated by Pasteur were taken from Paris to the Brown Institution, where, within a week, each developed the symptoms described as caused by rabies in rabbits It was now necessary to prove that this disease was communicable, and that it was rabies Without going into the details of the experiments, suffice it to say that they confirmed "the statement that the virus was contained in the spinal cord, that it could be transmitted without essential change by inoculation, that it was rendered more intense by transmission through rabbits, and that it might manifest itself either in the furious form commonly seen in dogs, or in the paralytic form usually seen in rabbits, or in intermediate forms, but that the disease was always the same—always true rabies" Pasteur's preliminary observations were thus proved to be correct, and the ground cleared for the experiments to test the claim that the virus could be so attenuated as to be inoculated without danger to animals, and that, when correctly used, it protects dogs against the effect of subsequent rabic inoculation Mr Horsley's investigations on this point also give sufficient evidence to show that Pasteur's claims are valid

And now as regards the mortality of persons treated by Pasteur's method The Commission, after taking account of sources of error in the statistics analyzed, conclude that the analysis is entirely in Pasteur's favor, they conclude that the method has saved a number of lives, "and that it is at present, and probably will be for long," the only mode of saving from death those who have been bitten by a rabid dog As regards the alleged dangers of Pasteur's method, as asserted by many of his opponents, the Commission decide in favor of Pasteur For an abstract of the report of the Commission the reader is referred to the "Special Article," immediately following the editorial columns in this issue Dr Lutaud's "M Pasteur et la Rage" is not worthy of an extended notice That he should have written a book of 458 pages to prove that some one else is a charlatan, and this without making any experiments, is of itself sufficient to show that Dr Lutaud is not an impartial critic In the absence of detailed experiments it would scarcely require so much writing to prove or disprove a theory, provided the critic were impartial

In his letter to the Medical Society of Vienna, Pasteur gives his special attention to von Frisch, as Gamaleia, of Odessa, has already pointed out the errors of De Renzi, Amoroso and Abren in the *Annales de l'Institut Pasteur* for March 25 Von Frisch, not very long after his return to Vienna from Pasteur's laboratory, published a communication on anti rabic inoculation, in which he claimed the initiative of anti rabic inoculation on dogs after they had been infected "subdurally" with street-rabies, whereas Pasteur says that he mentioned this very

matter to von Frisch when he was in Paris, and also mentioned them at the von Frisch's visit to Burdon Sanderson, Horsley and Gamaleia It will be remembered that von Frisch claimed that only by this method of infection, by "subdural" inoculation of street rabies, followed by anti rabic inoculation, was anyone in a position to form a judgment as to the value of Pasteur's work Pasteur claims that this statement is inexact, and Bardach, of Odessa, has confirmed the correctness of Pasteur's statements and results in this matter by ten successes out of fifteen experiments, Pasteur's statement being that anti rabic inoculation under such circumstances is quite different from anti-rabic inoculation after *subcutaneous* infection with street-rabies Then again, in most of his cases, and until his attention was called to his error, von Frisch used the slow method of inoculation in "subdural" infection, whereas the slow method is inappropriate on account of the quick course in "subdural" infection Furthermore, in his experiments on rabbits and dogs, with the view of ascertaining what influence anti-rabic inoculations, after the intensive method, had without preceding infection of the animals, von Frisch gives inoculation periods which do not correspond with Pasteur's experiments with "*virus fixe*," and he had many deaths from septicæmia, which Pasteur says is incompatible with a careful method of operating, and proof of the inaccuracy of his experiments After Pasteur's letter was read, Dr Ullmann made the following preliminary communication An experimental inquiry which, like that on rabies, requires such exact manifestation and such frequent repetition of the same series of experiments cannot be brought to a useful conclusion in a short time, and this accounts for the fact that I have waited till to day before giving a report to this learned Society the outcome of my experiments The following are my conclusions 1 According to the experiments which I have made, the animals do not die of rabies, owing to anti rabic inoculations 2 Certain animals can be protected against rabies by the anti rabic inoculations 3 The statistics of my anti rabic inoculations on men seem to be in favor of Pasteur's method

CLERGYMEN AND PATENT MEDICINES

It is now eighteen years since the late Dr S D Gross wrote what we believe was the first criticism of the endorsements of patent and quack medicines by clergymen, and of the advertisements of these swindles in religious papers But as the world grows older and, we hope, better, the tendency of clergymen to speak whereof they do not know (in regard to these things) seems to have increased rather than diminished It seems to be a curious coincidence that those clergymen who most frequently endorse patent medicines are those who are known as "popular" ministers, and whose names may be found in many daily newspapers and almost every magazine in the country as endorsing various brands of soap, stoves, pen wipers, and many other articles of which they cannot be supposed to know more than other people

The latest endorsement that we have seen is one of an extensively advertised stuff which has been christened "Vita Nuova," and which is claimed to cure all nervous troubles, dyspepsia, heart disease, sleeplessness, nausea, congestion, malaria, etc It is pleasing to know that it does not cure cancer The following endorsement is from "one of the most eminent divines of our day," says the advertisement, one who adds to his knowledge of "Vita Nuova" the title of "Prof"

DEAR FRIEND MRS AYER You and I have so long been personal friends that I am almost afraid that my regard for you helps make your "Vita Nuova" better than other medicines It finds in my organism an enemy that has "held the fort" for thirty years, but it has already brought me peace and hope It has great merit as a help to nature I am glad it is not a magical compound, nor the juice of some plant found in the heart of Africa by some heaven guided tramp, but is wholly rational and scientific With kindest wishes, your friend, —

"Wholly rational and scientific!" What would be thought of a physician who would publicly endorse a pumping machine as wholly in accord with mechanical laws? Of a lawyer who would display his name in a newspaper as endorsing some new surgical operation or treatment? Just what sensible people think of a clergyman who writes such endorsements as the above

MEDICAL RANK IN THE NAVY

Should this country become involved in a naval war, even with better war vessels than it now has, the service would be in an embarrassing position on account of the condition of the medical corps of the Navy A few months ago we called attention to the following paragraph in the "Report of the Surgeon-General of the Navy "Its vacancies have not been filled for several years, resignations, deaths, and retirements having depleted it more rapidly than candidates have been obtained It is impossible, with the present inducements offered, to find young men possessing the necessary qualifications who are disposed to become medical officers of the Navy

The Army Medical Department has qualified applicants far in excess of its needs, attracted by better pay, well defined rank, and more satisfactory professional position Since 1870 more than thirty young medical officers have resigned (three of them to enter the Army Corps) "

A very similar condition of affairs, so far as rank is concerned, now obtains in the British Army Relative rank has been abolished, and the profession of almost the whole British Empire is justly indignant And in regard to the condition of affairs in our Naval Medical Corps we may quote from an editorial in the *British Medical Journal*, of July 2 "Is it a wise and statesmanlike proceeding, all other considerations apart, to leave this wrong without a remedy? There can be but one answer to this question It is not wise, it is not statesmanlike Is it good to lower the self respect of the service? Is it good for the health and efficiency of the most costly army in the world, so to treat its officers as to scare from its ranks the very men a wise Minister should do all he reasonably can to attract into it?"

MEMBERSHIP IN THE CONGRESS —The Secretary-General of the Congress is prepared to promptly furnish all persons in other countries applying to him for registration, with a certificate of which the following is a copy

NINTH INTERNATIONAL MEDICAL CONGRESS
WASHINGTON, D C , 1887

Office of the Secretary General

This Certifies, That

is a Member of the Ninth International Medical Congress, and (with the members of his family), is entitled to the special rates of transportation to and from the Congress

JOHN B HAMILTON,
Secretary General

By

DUTY ON EXHIBITS FOR THE CONGRESS —In another column of this issue of THE JOURNAL will be found an important official letter from the Secretary of the Treasury of the U S , answering the many questions heretofore asked in reference to how far members of the International Medical Congress to convene in Washington, September 5, 1887, coming from other countries, could bring with them instruments, books, maps, or other materials to be used for illustrations in the work of the Congress, free from revenue taxes Our foreign exchanges would confer a favor by calling the attention of their readers to the facts stated in the letter

A VACANCY IN THE ILLINOIS STATE BOARD OF HEALTH —It has been announced in the daily papers that Dr George N Kreider, of Springfield, on the 18th inst sent his resignation to the Governor as a member of the State Board of Health, to take effect as soon as his successor was appointed and qualified No reasons are given for such resignation

SPECIAL ARTICLE

REPORT ON PASTEUR'S TREATMENT OF HYDROPHOBIA

[The report of the committee of the Local Government Board, appointed in April, 1886, to inquire into M Pasteur's treatment of hydrophobia, was presented to Parliament on June 27. We are indebted *The Lancet*, of July 2, for the following abstract of the report]

The report commences by stating that it was found necessary that some of the members of the committee should, together with Mr Victor Horsley, the secretary, visit Paris so as to obtain information from M Pasteur himself, to observe his method of treatment, and investigate a considerable number of cases of persons inoculated by him, and, further, that a careful series of experiments should be made by Mr Horsley on the effects of such inoculation on the lower animals Mr Horsley's experiments are stated to entirely confirm M Pasteur's discovery of a method by which animals may be protected from the infection of rabies If a dog, rabbit, or other animal be bitten by a rabid dog and die of rabies, a substance can be obtained from its spinal cord which, being inoculated into a healthy dog or other animal, will produce rabies similar to that which would have followed directly from the bite of a rabid animal, or differing only in that the period of incubation between the inoculation and the appearance of the characteristic symptoms of rabies may be altered The rabies thus transmitted by inoculation may, by similar inoculations, be transmitted through a succession of rabbits with marked increase of intensity But the virus in the spinal cord of rabbits that have died of inoculated rabies may be gradually attenuated by drying the cords, so that after a number of days' drying, it may be injected into healthy rabbits or other animals without any danger of producing rabies, and by using on each successive day the virus dried during a period shorter than that used on the previous day an animal may be made almost certainly secure against rabies, whether from a bite or from any method of subcutaneous inoculation, and this protection is proved by the fact that if animals so protected and others not thus protected be bitten by the same rabid animal, none of the first set will die of rabies, and, with rare exceptions, all of the second set will succumb

It may hence be deemed certain that M Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection from smallpox It would be difficult to over estimate the importance of the discovery,

whether for its practical utility, or for its application in general pathology It shows a new method of inoculation, or, as M Pasteur sometimes calls it, of vaccination, the like of which it may become possible to employ for protection of both men and domestic animals against others of the most intense kinds of virus The duration of the immunity conferred by inoculation is not yet determined, but during the two years that have passed since it was first proved there have been no indications of its being limited The preventive treatment adopted by M Pasteur is based on the foregoing experience, but the determination of the success of the method is far from easy, owing to—(1) the difficulty of determining whether the bites were really those of rabid animals, (2) the probability of hydrophobia in persons bitten by dogs that were certainly rabid depending very much on the number and character of the bites, whether they were on exposed parts or parts protected by clothing, and in all cases in the amount of bleeding, (3) in all cases the probability of infection may be affected by speedy cauterising or excision of the wounded parts, or by various washings, or other methods of treatment, (4) the unequal danger of bites of different species of animals, and even of different dogs In some groups of cases the percentage of deaths among persons bitten by dogs believed to have been rabid has been estimated at only 5 per cent, in others at 60 per cent, and the mortality from the bites of rabid wolves has been variously estimated at from 35 to 90 per cent

By the courtesy of M Pasteur, the committee were enabled to personally investigate ninety cases treated by him, these being mostly those which had been earliest treated, in which the periods since inoculation were longest, and living within reach in Paris Lyons, and St Etienne Among the ninety cases there were twenty four in which the patients were bitten on naked parts by undoubtedly rabid dogs, and the wounds were not cauterized or treated in any way likely to have prevented the action of the virus, there were thirty one in which there was no clear evidence that the dog was rabid, others in which the bite had been inflicted through clothes It is estimated, from experience of the result of bites in other cases, that had they not been inoculated, not less than eight among these ninety persons would have died Not one of them has shown since the inoculation any signs of hydrophobia

Since, in order to quiet fears, M Pasteur has been obliged to inoculate many in whom there was no satisfactory evidence that the bite was that of a rabid animal, it might be unjust to estimate the total value of his treatment in the whole of his cases as being more than the rate of mortality observed in them compared with the lowest rate observed in any large number of cases not inoculated This lowest rate may be taken at 5 per cent, and, as between October, 1885, and the end of December, 1886, M Pasteur inoculated 2,682 persons (including 127 from this country), the mortality should have been 130 But at the end of 1886 the number of deaths was 31, including 7 bitten by wolves, in whom the symptoms of hydrophobia appeared while they were under treatment, in fact, the actual percentage of mortality was betweeen 1 and 1 2, showing, on the lowest estimate, the saving of not less than 100 lives Of 233 persons bitten by animals in which rabies was proved, only 4 died Without inoculation, at least 40 would have died Among 186 bitten on the head or face by animals in which rabies was proved, only 9 died, instead of at least 40 Of 48 bitten by rabid wolves, only 9 died, instead of nearly 30 Between the end of last December and the end of March, M Pasteur inoculated 509 persons bitten by animals proved to have been rabid, only 2 have died, one of these, bitten by a wolf a month before inoculation, dying after only three days' treatment The committee think it, therefore, certain that the inoculations practiced by M Pasteur have prevented the occurrence of hydrophobia in a large proportion of those who, if they had not been so inoculated, would have died of that disease And his discovery shows that it may become possible to arrest by inoculation, even after infection, other diseases besides hydrophobia His researches have also added very largely to the knowledge of the pathology of hydrophobia, and supplied a sure means of determining whether an animal which has died under suspicion of rabies was really affected with that disease or not

The question whether the method itself entails risk to health or life is then discussed, the distinction between the ordinary method and the "intensive" method being pointed out By the first method there is no evidence or probability of any danger to health at all, but after the intensive method, which is only practiced in the most urgent cases, deaths have occurred which might possibly be attributed to the inoculation rather than to the original infection Yet in the worst cases the intensive method is relatively more efficacious than the ordinary method, nor is the rate of mortality greater after the former method than after the latter Certain cases, one of which is detailed, have, however, excited suspicion from the mode of death The case related is that of a man bitten by a rabid cat at the Brown Institution, treated by M Pasteur the next day by the intensive method, continued during twenty-four days, and dying about a month later with symptoms of acute ascending paralysis The man was very intemperate, and had been exposed to chill while crossing the Channel on his way home Mr Horsley proved that his death was due to the virus of rabies, by using a portion of his spinal cord for the inoculation of rabbits and dogs, who died with characteristic signs of paralytic rabies such as usually occurs in rabbits Yet it is by no means certain that the fatal issue in this and in other cases treated by the intensive method was not due to the original infection M Pasteur has, however, greatly modified this plan of treatment, which he employs in none but the most urgent cases

The final paragraphs of the report, which embody practical suggestions, may be given *in extenso*

The consideration of the whole subject has naturally raised the question whether rabies and hydrophobia can be prevented in this country If the protection by inoculation should prove permanent,

the disease might be suppressed by thus inoculating all dogs, but it is not probable that such inoculation would be voluntarily adopted by all owners of dogs, or could be enforced on them Police regulations would suffice if they could be rigidly enforced But to make them effective it would be necessary (1) that they should order the destruction, under certain conditions, of all dogs having no owners and wandering in either town or country, (2) that the keeping of useless dogs should be discouraged by taxation or other means, (3) that the bringing of dogs from countries in which rabies is prevalent should be forbidden or subject to quarantine, (4) that in districts or countries where rabies is prevalent the use of muzzles should be compulsory, and dogs out of doors, if not muzzled or led, should be taken by the police as "suspected" An exception might be made for sheep dogs and others while actually engaged in the purposes for which they are kept There are examples sufficient to prove that by these or similar regulations rabies, and consequently hydrophobia, would be in this country "stamped out," or reduced to an amount very far less than has hitherto been known If it be not thus reduced, it may be deemed certain that a large number of persons will, every year, require treatment by the method of M Pasteur The average annual number of deaths from hydrophobia during the ten years ending 1885 was, in all England, 43, in London alone 8 5 If, as in the estimates used for judging the utility of that method of treatment, these numbers are taken as representing only 5 per cent of the persons bitten, the preventive treatment will be required for 860 persons in all England, for 170 in London alone For it will not be possible to say which among the whole number bitten are not in danger of hydrophobia, and the methods of prevention by cautery, excision, or other treatment cannot be depended upon

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, April 6, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR SWAN M BURNETT presented a specimen and gave the history of a case of

EXTRACTION OF BLACK CATARACT FROM THE ANTERIOR CHAMBER

The patient, a woman of 39, but who looks to be 45, was seen by him several months ago She reports that for several years she has been blind in the right eye, and that now she could not see with the left eye For several months she has suffered great pain in the left eye Examination proved that there was a black cataract in each eye, and that the lens of the left eye was dislocated into the anterior chamber This is a serious complication and usually means enucleation, but extraction is sometimes possible She was sent to the Garfield Hospital and the operation of extraction was performed under general anæsthesia The danger in this condition is that the lens will slip back into the posterior chamber To prevent this escape the "bident" of Dr Agnew, of N Y is used This consists of two fine needles, mounted close together in a handle, which are struck through the cornea behind the dislocated lens, thus preventing its slipping backwards In this case the bident being an imperfect one, he could not use it Although the anterior chamber of the left eye was full of blood he made a slight incision, as for cataract, and enlarged it with the scissors that he might not disturb the lens

There was no escape of the vitreous humor, and the woman is now doing well There appears to be two forms of this peculiar cataract, c nigra and c pigmentosa This latter form usually consists of a deposit of pigment in the lens proper, but that has been proved not to be so in his two cases

DR BURNETT presented a specimen of

BONY FORMATION IN THE EYE

The patient, a male, was injured in the right eye by some blunt instrument about seventeen years ago The sight was not at first impaired, but repeated attacks of inflammation with great pain compelled him to seek advice from a doctor After a few weeks treatment the right eye was no better, and the left eye began to hurt him Dr Burnett sent him to the Garfield Hospital, and under general anæsthesia he found that the right eye was deformed and hard, and that there was iritis of the left eye He enucleated the right eye and performed iridectomy on the left The left eye is still much inflamed and it is probable that he will never be able to see out of it The inflammation is undoubtedly sympathetic from the long continued trouble in the other eye, and if the right eye had been removed sooner it is probable that the left could have been saved

There is no doubt that the deposit is bone, but it is in rather an unusual place, being in the choroid, and occupying the place of the vitreous humor

DR D S LAMB also presented a specimen of

BONY FORMATION IN THE EYE

Dr Lamb said that the case was similar to Dr Burnett's, only he did not know the history as the eye was removed at an autopsy upon a man of 75 He believed that the trouble began with an injury The eye is shrunken and the bony formation is cupped in front where the crystaline lens lay The left eye showed sympathetic inflammation with opacity of the cornea

DR LACHLAN TYLER read a paper entitled

DIPHTHERIA AND TRACHEOTOMY,

(which will be published in an early issue)

DR F C FERNALD then read a paper entitled *Three Unusual Cases of Diphtheria*

FOREIGN CORRESPONDENCE

LETTER FROM GOETTINGEN [1]

Koenig and Rosenbach—Goettingen Polyclinic—Empyema—Amputation of Thigh for Osteomyelitis

My Dear Dr Fenger —In my last letter I promised to relate to you this time the results of my observations in Goettingen You are aware that in our weekly colloquium at your house after my lectures Friday evenings, we have mentioned the names of Koenig and Rosenbach perhaps more frequently than the names of any other two surgeons This was not accidental by any means, as Koenig occupies by common consent a foremost position in the list of the most prominent surgeons of Germany, a distinction he well deserves as the author of the best text-book on surgery, as a clear and impressive teacher, as an accurate clinical observer, as a bold and successful operator, and last, but not least, as a perfect type of a gentleman, while the name of Rosenbach is intimately associated with the scientific part of surgery, more especially the etiology of suppuration, the nature of osteomyelitis and the microbic origin of tetanus Ogston and Rosenbach, who have both distinguished themselves by their investigations concerning the influence of pus microbes in the causation of suppuration, resemble each other very closely in many respects Both are about the same age, both are hard and enthusiastic workers, and both are extremely modest men There is perhaps not a second medical school in the world where the teachers of surgery work more harmoniously and efficiently than in Goettingen Koenig, still active and energetic, perfectly familiar with surgical literature and with an enormous clinical experience, teaches practical surgery in such a manner that students become fascinated in the subject and perfectly grounded in this part of their professional study, while Rosenbach, who looks at everything from a scientific standpoint, stimulates students by his own example and teaching to follow him through the most profound and difficult topics in surgical pathology A student who graduates from this university should be a good surgeon, and if this is not the case he has certainly not made the best of his opportunities Soon after my arrival in Goettingen Prof Rosenbach called on me at the hotel, and after a pleasant chat we called on Prof Koenig at his own house We found him in his study dressed in a hunting jacket, surrounded by books, pamphlets and journals Behind his desk I noticed an extensive collection of smoking pipes systematically arranged on a rack The collection embraced large pipes and small pipes, pipes with short stems and pipes with long stems, meerschaum pipes and porcelain pipes, and each specimen presented evidences that this array of pipes was not intended for ornamental purposes, but for comfort and enjoyment during the long hours devoted to literary study and work Prof Koenig is now 57 years of age, in vigorous health both mentally and physically The tooth of time has claimed the hair on the top of his head, but otherwise has produced no visible effects He is a little above average height, compactly built, with a well shaped head and intelligent face, which under all conditions and under all circumstances is expressive of great determination He is a great hunter, and when he feels himself worn out and tired he finds healthful recreation on his hunting grounds in following the hare or the nobler game in the mountains I found him a most genial gentleman, always anxious to learn himself when brought in contact with others, and ever willing to impart knowledge to all who came to him for this purpose I remained three days in Goettingen, and it would be difficult to imagine a place where I could have employed my time in a more interesting and profitable manner The General Hospital is an old building, but the surgical wards are comfortable and afford room for 120 patients As the city is small, cases of accident are few, but the wards are filled with patients suffering from all kinds of tubercular affections, tumors and deformities The operating room is small but fully equipped with all modern improvements for the antiseptic treatment of wounds The supply of instruments in this klinik is characteristic Prof Koenig makes it a rule to perform operations with few and very simple instruments An examination of the drawers containing the instruments reminded me of a carpenter shop, as they contain a good assortment of carpenter's chisels and mallets, common drills for perforating bone, ordinary large scissors for cutting gauze and bandages, small saws and large saws, and large scissors for cutting bone which are used in the vineyards for pruning purposes, spring forceps with sharp teeth is used in preference to other forms of hæmostatic forceps, sharp spoons, from the smallest size to near as large as the palm of the hand, are present in large numbers, and suggest the frequency with which tubercular lesions are submitted to operative measures, most of the larger spoons are fenestrated Corrosive sublimate is used for irrigation, and sublimated gauze for dressing

Professor Rosenbach has charge of the polyclinic where every forenoon a large material is presented and where numerous minor operations are performed and proper material for the hospital selected The result of my observations have satisfied me that these polyclinics are not sufficiently frequented by the students The average medical student has an intrinsic desire to witness capital operations, and does not take sufficient interest in minor cases When we recollect that only a fractional number of the thousands of medical students really become surgeons, but that all will have to depend in their future practice for their daily bread on the treatment of small, to them now unimportant things, it becomes evident that a grave mistake is committed in not making the attendance of polyclinics compulsory and a part of the curriculum of study Teachers of surgery, as a rule, are only happy when they can present to their classes interesting, rare cases, or perform capital operations, and often deem it beneath their dignity to consume an occasional hour in the discussion of a contusion, a furuncle, a paranitium, a wart, or some other

[1] By permission of Drs Fenger and Senn

insignificant topic that nevertheless may affect the comfort and happiness of patients who will seek not the distinguished surgeons of metropolitan cities for relief, but who will apply for treatment to their family physicians Many distinguished operators who perform the most difficult and critical operations in a perfect and blameless manner have been known to treat unimportant cases badly The clinical teacher who complains of a lack of material is always hunting up big cases, and is only contented when he finds a case of stone, an abscess of the brain or lungs, an aneurism of some large artery, or some other pathological condition which will necessitate a brilliant operation, which perhaps not one of his students will ever be called upon to perform

Men like Rosenbach can make a polyclinic what it should be—a stepping stone, a preparatory course to the regular surgical clinic During one forenoon a lad was brought into the polyclinic suffering from great dyspnœa, with a history that he had been ill for several weeks He had been treated for pleuropneumonia, and as resolution did not set in at the right time, different counter irritants were applied successively without producing the desired effect A physical examination of the chest revealed the existence of a copious effusion into the left side of the chest, which dislocated the heart so that the apex beat could be distinctly seen under the nipple on the right side The diagnosis of empyema was made without resorting to an exploratory puncture, from the history of the case and signs and symptoms which were presented at the time As further loss of time was considered dangerous, the radical operation was performed at once by Prof Rosenbach Chloroform was administered and about an inch of the fifth rib in the axillary line resected subperiosteally, the pleura incised and the cavity drained At least two quarts of pus escaped No irrigation, a copious dry sublimated gauze dressing

During the same forenoon, in the absence of Prof Koenig, an amputation was made by Dr Mueller, first assistant of the surgical clinic As this case is of great interest from a clinical and pathological standpoint, I will give it somewhat in detail The patient was a man about 35 years of age who, without any apparent cause, was attacked four weeks ago with acute osteo myelitis of the tibia As soon as he was brought into the hospital, about a week after the commencement of the attack, Prof Koenig chiseled the entire shaft open, and found that the disease had involved the ankle joint, which was opened and drained at the same time The knee joint was greatly swollen, and, as no direct communication could be traced between it and the suppurating medullary canal, it was explored and, as pus was found, it was incised and drained As this extensive operation did not succeed in reducing the temperature or otherwise improving the general condition of the patient, amputation was advised as the only means to fulfil an *indicatio vitalis* The operation was rendered nearly bloodless by elevation of limb and circular elastic constriction of upper portion of thigh Antero posterior cutaneous flaps were made, and the cut surface of the bone covered with a cylindrical periosteal flap One deep catgut suture was introduced to prevent muscular retraction A large gauze drain was introduced transversely in the wound, over which the skin flaps were fastened with only two sutures Accurate suturing of wounds is considered as unnecessary, and often as injurious, in this clinic It is claimed that when only few sutures are used better drainage is secured, and the wound heals as kindly and with as good a cicatrix as after the most careful suturing Unless contraindications arise the first dressing is allowed to remain for a week, when the drain is removed, after which the wound heals rapidly by granulation The thick gauze compress is covered with wax paper as an impermeable covering Before each operation the blades of the instruments are thoroughly wiped with an aseptic cloth, and their handles washed with a 4 per cent solution of carbolic acid N SENN

(*To be concluded*)

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Incompatibility of Calomel and Bromide of Potassium—Bergeon's Method—Inconveniences of Iodoform—Cocaine Accidents

In a note by M Pierre Vigier in the *Gazette Hebdomadaire* the author brings to notice the incompatibility of the bromide of potassium and calomel If, states the author, a few drops of a concentrated solution of the iodide of potassium be poured on calomel, the latter becomes green, that is to say, the mixture becomes a proto iodide of mercury This incompatibility is well known, and consequently great care is taken that these salts are not prescribed together, nor even after a short interval between them The same precautions should be taken with the bromide of potassium, though the reaction between it and calomel is less than that between the latter and the iodide of potassium Owing to the knowledge of this fact no medical man would prescribe the two drugs together, nor would he leave an interval of less than five or six hours between their administration, but cases may present, convulsions in children in instance, in which two physicans may have been called in successively, and where the first having prescribed calomel, the other would prescribe the bromide of potassium The serious accidents that may result from this medication may well be imagined, and this is one reason why M Vigier thought it necessary to bring it before the profession

Dr Desplats, of Lille, has reported to the medical society of that town that of five phthisical patients that he had submitted to the method of treatment by gaseous enemata, the results were as follows Three completely unsuccessful, relief of the dyspnœa in one case, and in one instance only has there been a rapid improvement in the general state of the patient This patient, however, had, at the time the treatment was employed, an attack of pleuro pneumonia, and the defervescence coincided with the application of that treatment, which Dr Desplats considers quite inefficacious in any form of pulmonary phthisis, and much more so in the acute form

The gaseous enemata have, however, an immediate action the relief of the dyspnœa in relation to the influence exercised on the bulb by the carbonic acid and to the experiments of Professor Brown Séquard, and a tardy action, attributed by some to the sulphuretted hydrogen and the sulphuret of carbon, and by others to the carbonic acid the sulphur waters contain The general impression among the profession in this country is that the treatment of phthisis by Bergeon's method does not possess sufficient advantages to supersede the other methods in vogue, though it may be employed as a simple palliative But even this property will not counterbalance the drawbacks of the method, to wit, the inconvenience that patients are put to by the frequent use of the enema, and their exposure to the risk of entero-colitis, which has been attributed to it

Iodoform is an agent very much in vogue internally, as well as externally, as an anti parasitic and antiseptic Dr A Poncet, of Lyons, in a paper read before the surgical society of that city, related the inconveniences arising from dressings with that substance Iodoform excites, particularly in women, an anorexia, the more intense according as the habits of the patients are more civilized or refined The odor itself is a great drawback, and however the drug may be disguised it is always readily recognizable The patients lose all taste for food, which is attributed to the presence in the saliva of iodides and of alkaline iodates Dr Poncet remarks that the buccal cavity is probably not the only medium of the elimination of iodoform, the intestinal mucous membrane and the kidneys serve as emunctories The odor of this substance is often recognized in the sudorous secretions The author points out the affinity that silver has for this substance, so much so that all utensils composed of this metal and used by patients saturated with iodoform become infected with the peculiar fœtid and garlic odor, in consequence of which patients who are acquainted with this fact, adopt iron spoons and forks instead of silver In patients under treatment with iodoform, but who are not yet saturated with it, the peculiar odor of the drug may nevertheless be developed by simply placing a piece of silver in contact with the saliva of the patient, then rubbing it with a piece of linen, the metal gives out the well known odor This the author terms the *signe de l'argent* The researches of Dr Cazeneuve show that the garlic odor disengaged by silver in contact with iodoform is due to the production of the iodide of silver with the formation of acetylene

As every medal has its reverse so has cocaine, so much vaunted lately It has rendered great service in a variety of circumstances for the prevention and relief of pain, but several severe accidents having occurred by its administration Dr Dujardin Beaumetz has thought proper to publish in the *Bulletin de Therapeutique* a paper communicated by Dr Bignon, of Lima, who gives the following results of a series of experiments performed by him on man and dogs with cocaine 1 Cocaine produces only physiological effects, which are very transitory, in doses of from 30 to 50 centigrammes administered by the stomach, on condition that the drug be absorbed in divided doses of five centigrammes every hour 2 It acts principally on the renal secretion in retarding it, in preventing the elimination partly of the products of oxidation, and in then producing the first symptoms of slight uræmia 3 In a single large dose it produces anuria followed by grave uræmic accidents (nervous convulsive attacks etc) 4 This paralyzing action of cocaine on the kidneys generally disappears two or three hours after the absorption of the alkaloid It is followed by a considerable diuresis which relieves the organism, and which is the more active according as the anuria had been much prolonged 5 Cocaine is toxic only in an indirect manner when the dose is sufficiently high to prolong anuria, to the extent of the accumulation of toxic products of the urine, in sufficient quantity to produce symptoms of uræmic poisoning 6 If the diuresis should make the toxic phenomena to disappear rapidly, the general stimulating action continues none the less for a long time afterwards It lasts about twenty four hours at fifty centigrammes in the day During all this time the phenomena of oxidation continue to go beyond the normal average, denutrition, in a word, continues To sum up, cocaine acts in two ways 1 In diminishing the renal secretion, and, if the dose is sufficiently high, in suppressing it during a sufficient time to produce the gravest uræmic accidents, and even death in a very short time 2 In hastening nutrition, and then the production of the products of disassimilation or of oxidation If, then, the dose is high, the two actions combining contribute to cause death in a very little time by uræmic accidents If, on the contrary, the doses are divided, they leave between each the necessary time for the reaction (diuresis), and death will only be the consequence of prolonged exhaustion and decentration A B

DOMESTIC CORRESPONDENCE

BERGEON'S METHOD

Dear Sir —In THE JOURNAL of June 18, 1887, p 676, in the body of the "Address in Medicine" by Dr J S Lynch, I find the following (I do not wish to be regarded as a champion of the Bergeon treatment of tuberculosis)

> For, admitting all that is claimed as to the agency of microbes in setting up and keeping up disease processes, it must be remembered that they are biologically as high in the plane of life, and if all experiments can be believed, have a higher resisting power than the cells which compose the living elements of our tissues *Any germicide therefore, which can destroy the one, must inevitably destroy the other*

I am of the opinion that the above reasoning is faulty and would lead young practitioners astray In vol xvii, page 662, Ziemssen's Cyclopædia of Practice of Medicine we find the following "*Cases of* poisoning have also been recorded, from human beings eating the flesh of animals, which had fed upon belladonna leaves without danger to themselves, among the animals to which atropia is innocuous are

rabbits, pigeons, rats and guinea pigs" Snails are also said not to be affected by it

We have been informed that sulphate of strychnia, in the dose of thirty to sixty grains will not kill a hog It must also be a patent fact that solanine will not kill potato bugs, while it is certain to kill a man We also wish to call attention to the fact that the dose of veratrum viride that would be harmless to a white man, would be a very dangerous one to give a negro It is also known that on the other hand santonine is practically non poisonous to the human family, while it readily kills intestinal parasites

I do not wish to plead for or against the treatment of tubercle by gaseous enemeta but from Dr Lynch's remarks I believe that he has placed the cart before the horse, as you read from line 19, page 676, of THE JOURNAL

Even then, admitting that his mixed gases can destroy the microbes, which seems highly improbable, in view of the fact that, they are continually exposed to an atmosphere so highly charged with *carbonic dioxide* that its retention in the lungs for five minutes will produce unconsciousness, it is not clear how they are to reach the objects intended to be destroyed

If I understand the theory set forth by Bergeon, it is the sulphuretted gases that do the work, and the carbon dioxide is used as a diluent to carry the sulp hydric acid gas to the scene of trouble in such con dition that it shall not cause erosion of the mucous membrane of the bowels or other tissues with which it may come in contact

In the treatment of pulmonary tubercle, who has seen any marked effect from any kind of treatment? Let us be cautious in making experiments with this plan of treatment, and if any benefit can be secured from the so called gaseous enemata we would like to know it, if not, lay it away in its sarcophagus to rest with the dead

I think Dr Lynch would have us believe that what is life to one, is life to all, and that that which will kill one form of animal life will kill all forms But as a matter of fact this is far from being true, as will be seen from the above quotations Even among pa tients in the same family, we find that that which will favor life and health in one member, if continued, would produce disease and ultimately death in an other of the same blood Why it is we do not know The unknown quantities in the equation of life as yet have not all been solved, and much may be learned from empiricism ORSON MILLARD, M D

Flint, Mich., June 27

POISONING BY POKE ROOT

Dear Sir —On the evening of March 25, 1887, I was called in haste to see J H , a stout, muscular colored man, 39 years of age, who was said to have been suddenly attacked with "vomiting and cramps in his bowels" I obtained the following history from him In the afternoon an old vender of domestic medicines was in the city, with among other things, a large quantity of poke root, which he said was good when put in whiskey to purify the blood My patient asked him if it was not good to chew also, and upon receiving an affirmative answer, placed a small piece—probably ʒj or ʒij—in his mouth and began to chew it and swallow the juice This was about 3 30 P M About one hour later, being thirsty, he drank a pint of cold water and shortly afterwards nausea set in, soon followed by vomiting, at first of the contents of the stomach and then of a greenish colored and very bitter fluid He continued to vomit frequently till 7 P M when he began to have severe pain in his bowels, accompanied by free purgation and hematemesis

When I first saw him, at 7 30 P M , he complained of heaviness in the head and dizziness, was suffering severely from pain in the abdomen, and said he felt as though there was a hard lump in his stomach He was considerably prostrated and sweating freely, pulse 90, soft and compressible At 8 P M I gave him subnit bismuth, gr x, morph sulph gr ⅓, and ordered it to be repeated in half an hour if he obtained no relief and also to have hot, dry woolen cloths applied to his abdomen, and allay his thirst with mucilaginous drinks At 9 P M I saw him again He was a little easier, but had vomited three times in the interim, and each time a considerable quantity of blood I now gave him morph sulp gr ¼ dissolved in a little cold water, after which the pain soon subsided He vomited twice during the succeeding hour, then fell asleep and awoke the next morning comparatively well ALEXANDER GUTHRIE, M D

Cairo, Illinois

TREATMENT OF DYSPEPSIA

Dear Sir —In THE JOURNAL of July 2 is an article giving Dr Talma's treatment of dyspepsia with hydrochloric acid For the last twelve years I have met with almost unlimited success in treating dyspepsia with this agent, though I perhaps use it in stronger solution than Dr Talma I use it in the proportion of about ʒij nitro muriatic acid to ʒiv water, believing that the combination of the two acids is better than one alone I invariably give the solution in tea spoonful doses immediately after meals I have treated some of the most severe cases, and have cured some of the most obstinate, with this combination

When the heart is sympathetically affected I have used tinct digitalis, gtt v–vj, three times a day with good results

When there is constipation I have of late had excellent results from a combination of cascara sagrada and fluid extract juglans cinerea, teaspoonful three times a day I insist that my patients should abstain from tea and coffee, and use either water or milk, especially buttermilk, which seems to have an excellent effect upon the stomach and alimentary canal generally, giving health and vigor to the absorbent vessels

When there is much gastric distress after eating a few drops of chloroform will soon relieve the pain

In severe cases of gastralgia there is nothing better, in many cases, than oil of cojeput, gtt v–vj

In cases of vomiting, chloroform has a soothing effect, and sometimes a small dose of morphia has a good effect in quieting the nervous system Or a mustard plaster or horse radish leaves may be used

In some cases in which the patient uses tobacco I forbid it, and the patient gets well without medicine

Harmon, Ill , July 5 WM HENRY, M D

INTERNATIONAL CONGRESS.

GENERAL PROGRAMME OF THE CONGRESS

As there appears to be a very general desire, both at home and abroad, to have the programme of arrangements for the meeting of the International Medical Congress made public, I herewith submit the formula therefor determined upon by the Committee of Arrangements intrusted with that duty

FIRST DAY—MONDAY, SEPTEMBER 5

The Congress will assemble at Albaugh's Opera House at 11 A M, and will be formally opened by the President of the United States, to be followed by a short address of welcome by the Secretary of State, Address by the President of the Congress, Report of Secretary-General and Chairman of Committee of Arrangements Adjourn at 1 30 P M From 3 to 6 P M, meeting of the Sections at their respective halls Evening *conversazione* at U S Pension Hall from 8 to 11 P M

SECOND DAY—TUESDAY, SEPTEMBER 6

Meeting at 10 A M at Albaugh's Opera House General Addresses by Drs Flint and Semmola Sections will meet at 11 A M, and adjourn at the same hour with Congress at 1 P M In the afternoon the Sections will meet from 3 to 6 P M In the evening it is expected that a reception will be given by the President of the United States, and the Corcoran Art Gallery will be thrown open to the members and their families

THIRD DAY—WEDNESDAY, SEPTEMBER 7

The Congress will meet at 10 A M General Addresses until 1 P M The Sections will meet as usual at 11 A M, and adjourn at 1 P M Afternoon meeting of the Sections from 3 to 6 P M Evening reception to the members and their families by the citizens of Washington

FOURTH DAY—THURSDAY, 8TH

General meeting at 10 A M Addresses, if not previously delivered Meeting of the Sections at 11 A M, adjourn at 1 P M Afternoon, Sections meet from 3 to 6 P M General reception buffet banquet at U S Pension Hall from 8 to 11 P M

FIFTH DAY—FRIDAY, 9TH

General meeting at 10 A M Transaction of business affairs of Congress Meeting of Sections at 11, and adjourn at 1 P M Afternoon, Sections meet from 3 to 6 P M

SIXTH DAY—SATURDAY, 10TH

General meeting at 10 A M Adjourn at 11 for visit to Mt Vernon

On Sunday or Monday, the day not yet determined upon, an excursion train will leave Washington with the foreign members and their families for Niagara Falls, under the escort of a part of the committee of arrangements, selecting the route which will afford our foreign brethren an opportunity to see some of the most interesting and thrifty portions of our country, as well as very beautiful scenery

In completing the details of this programme it may be necessary to make some slight modifications

I send herewith an important communication from the Chairman of the Sub Committee on Transportation, Dr J W H Lovejoy

ALEX Y P GARNETT, M D,
Chairman of Committee of Arrangements

RAILWAY RATES TO WASHINGTON.—The Railroad Associations which have already agreed to make a reduction of fare for members of the Congress and their families on the roads under their control are

The Trunk Line Association

The Central Traffic Association

The Newport News and Mississipi Valley Company

The Southern Passenger Association

These cover the greater part of the territory east of the Missouri and Mississipi rivers The whole list of roads controlled by these Associations is too large for publication, but members can obtain all the necessary information by application to the railroad agent at the starting point It will be required to pay full fare to Washington and a return will be allowed for "one-third the highest limited fare" on the Association's certificate It will be necessary for these certificates to be procured before starting and have upon them the receipt of the railroad agent for the full fare to Washington Members intending to attend the Congress should, as soon as possible, make application to the undersigned for blank certificates of the Association over whose roads they intend to travel, and the blanks will be forwarded at as early a date as they can be obtained A separate certificate will be required for each person

J W H LOVEJOY, M D,
Chairman Transportation Committee

DUTY ON EXHIBITS FOR THE CONGRESS

[The following letter from the Secretary of the Treasury to Dr John B Hamilton, Secretary-General of the Ninth International Medical Congress, is of especial interest to our foreign confrères who wish to attend the Congress]

Sir In reply to the inquiries contained in the letter of F H Rehwinkel, M D, referred by you to this department, I have to state that the professional books, implements, instruments, of persons arriving in the United States are exempt from duty under the provisions of the tariff law, which also provides for the free admission of "models of inventions and other improvements in the arts, such as cannot be fitted for use," and that parties arriving from foreign countries for the purpose of attending the Ninth International Medical Congress, to meet at Washington September 5, 1887, and who bring with them their own "surgical or dental instruments, scientific and mechanical appliances, models and materials to be used for clinical demonstration under the direction of said Congress," will be entitled to have the same passed free of duty,

on the usual oath that they are for their personal use and are not intended for sale

As it would appear from the act of Congress relative to said convention that the said Ninth International Medical Congress is a society established for philosophical and scientific purposes—books, maps and charts (not more than two copies in any one invoice), philosophical and scientific apparatus, instruments and preparations, casts, paintings, drawings and etchings, specially imported in good faith for the use of said Congress and not intended for sale, would also seem to be entitled to free entry under the provisions of the tariff act now in force, a copy of which is herewith enclosed (See paragraphs 660, 759 and 815)

Copies of this letter will be transmitted to the Collectors at the principal ports for their information and guidance Respectfully yours,

(Signed) C S FAIRCHILD,
Secretary of the Treasury

BOOK REVIEWS

LEHRBUCH DER KINDERKRANKHEITEN Von Prof DR ALFRED VOGEL in Munchen Neunte Auflage, neu bearbeitet von DR PHILIP BIEDERT, Oberarzt am Burgerspital und Kreizazrt in Hagenau Mit 6 lith Tafeln 8vo, pp xvi 600 Stuttgart Verlag von Ferdinand Enke, 1887

DISEASES OF CHILDREN By PROF DR ALFRED VOGEL, of Munich Ninth edition, newly revised by DR PHILIP BIEDERT, of Hagenau With 6 lithograph plates Stuttgart Ferdinand Enke, 1887 Chicago Koelling, Klappenbach & Kenkel

It is just twenty years since the first edition of this work was issued, and the appearance of the ninth edition now shows that it was not written in vain For several years the book has been favorably known to and received by English reading medical men through translations The very thorough revision to which the book was subjected two years ago by the author has precluded any very essential changes in the present edition For the benefit of those who are not already acquainted with the work the following summary of its contents may be of interest The general part consists of four chapters, which deal with "physiological and anatomical structure of the infantile organism," "general rules for the examination of children," "treatment and medication of children in general," and the "feeding and care of children" The special part consists of nine chapters, dealing with "diseases arising from labor," "diseases of the digestive apparatus," "diseases of the respiratory organs," "of the circulatory organs," "of the nervous system," "of the urinary and genital organs," "of the skin," "general diseases, dyscrasiæ," and "diseases of the organs of locomotion" Professor Vogel's book has passed the stage of criticism, and as 'good wine needs no bush," so it needs neither analysis nor commendation at our hands

ELEMENTS OF PHYSIOLOGICAL PSYCHOLOGY A Treatise on the Activities and Nature of the Mind from the Physical and Experimental Point of View By GEORGE T LADD, Professor of Philosophy in Yale University 8vo, pp xii 696 New York Chas Scribner's Sons, 1887 Chicago A C McClurg & Co

Professor Ladd has set himself the task of putting forth the assured or alleged results of Physiological Psychology, keeping in view the belief that there is no ground for extravagant claims or expectations, and still less ground for any fear of consequences, in the way of falling upon something which would prove that perhaps, after all, man is not a spiritual and rational being The book which he gives us is the first fruit of American work in this field, which covers the whole subject, and with the exception of Wundt (Grundzuge der physiologischen Psychologie), there is no other work at all which even attempts to cover the entire ground How well the territory has been covered is difficult to show in a short notice of a work on so comprehensive a subject Throughout the book it is apparent that the author's aim is to get at the truth, or as near to it as possible, not only by following known roads, but also by exploring unknown by paths It is a most carefully written book, and cannot fail to interest one at all partial to a study of philosophy and of physiology of the mind

ANATOMY, DESCRIPTIVE AND TOPOGRAPHICAL, in 625 Illustrations By CARL HEITZMANN, M D English edition by LOUIS HEITZMANN, M D 8vo, pp xxii 238 270 36 Vienna W Braumuller New York J H Vail & Co, 1887

The fact that more than 30,000 copies of Heitzmann's "Anatomischer Atlas," the basis of this work, have been sold in the last sixteen years in Germany should be taken as evidence that the work is a good one And yet we cannot consider a work on anatomy complete unless it takes some account of anomalies, and anomalies are not mentioned in this book, except some of those of the branches of the arch of the aorta and in the course of the obturator artery As a guide to dissection it might answer very well, but in its present shape and style its title is a misleading misnomer

WHAT TO DO IN CASES OF POISONING By WILLIAM MURRELL, M D, F R C P, Lecturer on Pharmacology and Therapeutics in the Westminster Hospital, etc First American from Fifth English edition Edited by Frank Woodbury, M D, Professor of Materia Medica, Therapeutics, and of Clinical Medicine in the Medico Chirurgical College of Philadelphia Sm 8vo, pp 158 Philadelphia The Medical Register Co, 1887

Dr Murrell is a very terse writer The preface to this little book shows that he wastes no words "A complaint has been made that the book is getting too big I admit it, but the fact is, there are too many poisons now a days If people who contemplate committing suicide would only adopt a uniform method it would facilitate matters greatly" Of

course a book on the treatment of poisoning by Dr Murrell is almost entirely based on a thorough knowledge of pharmacology; and he rightly says that one who forgets the antidotes to poisons cannot have a proper knowledge of this important branch of medicine

The book is conveniently arranged for ready reference, and besides the bald facts of treatment contains many useful suggestions With the exception of one particular it seems to be complete no mention is made of transfusion in gas poisoning, and this must be regarded as a serious defect

A TREATISE ON SIMPLE AND COMPOUND OPHTHALMIC LENSES, their Refraction and Dioptric Formulæ, including Tables of Crossed Cylinders and their Sphero Cylindrical Equivalents By CHAS F PRENTICE Publishers, James Prentice & Son, Opticians, 179 Broadway, New York

This is a neatly printed and abundantly illustrated little volume of 40 pages The contents of the volume are well indicated in the above title, and the style of the author is simple, and his methods of illustration easily understood

MISCELLANEOUS.

HEALTH IN MICHIGAN, JUNE, 1887 —For the month of June, 1887, compared with the preceding month, the reports indicate that diarrhœa cholera morbus, intermittent fever and cholera infantum increased, and that pneumonia, influenza, bronchitis, tonsilitis and measles decreased in prevalence Compared with the preceding month, the temperature in the month of June, 1887, was higher, the absolute humidity was more, the relative humidity was slightly more, the day and the night ozone were less Compared with the average for the month of June in the nine years 1879-1887, neuralgia increased, and intermittent fever, remittent fever, consumption of lungs, scarlet fever, diphtheria and bronchitis were less prevalent in June, 1887

For the month of June, 1887, compared with the average of corresponding months in the nine years 1879-1877, the temperature was slightly higher, the absolute and the relative humidity were slightly more, and the day and the night ozone were slightly less

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of June, 1887, at thirty nine places, scarlet fever at forty two places, typhoid fever at twelve places, measles at thirty six places, smallpox and typhus fever at one place Reports from all sources show diphtheria reported at nine places more, scarlet fever at ten places more, typhoid fever at eight places more, measles at fourteen places less, and smallpox and typhus fever each at one place more in the month of June, 1887, than in the preceding month

THE ALUMNI ASSOCIATION PRIZE OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY —This prize of $500, open to the Alumni of the College, will be awarded to the best *medical essay* submitted to the Committee, upon any subject the author may select Essay must contain the results of original investigations or research made by the writer Each essay must be marked with a device or motto, and accompanied by a sealed envelope similarly marked, containing the name and address of the writer Essays for the prize to be awarded in May, 1888, must be sent to a member of the Committee, on or before April 1, 1888 ANDREW J MCCOSH, M D, WILLIAM G THOMPSON, M D and M ALLEN STARR, M D, are the Committee

DR HARVEY REED, of Mansfield, O, has been appointed Surgeon in Chief of Trans Ohio Division of the Baltimore & Ohio Railroad

THE HOT WEATHER IN CHICAGO —From the effects of the heat of last Friday, Saturday and Sunday 165 people died in this city For the week the deaths from insolation number more than one fourth of the total number of deaths

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JULY 9 1887, TO JULY 15 1887

Lt Col A Heger, Surgeon, ordered to Ft Columbus, New York Harbor

Major J H Janeway, Surgeon, ordered to Benicia Bks as Post Surgeon, also as attending surgeon at Benicia Arsenal, Cal

Capt H P Birmingham, Asst Surgeon, ordered to Ft Myer, Va

First Lieut C E Woodruff, Asst Surgeon, ordered to Ft Mackinaw, Mich

Capt C K Winne, Asst Surgeon, ordered to Ft Wadsworth, New York Harbor

Capt Valery Havard, Asst Surgeon, ordered to Ft A Lincoln, D T

Capt L M Maus, Asst Surgeon, ordered to Ft Schuyler, New York Harbor

Capt J B Girard, Asst Surgeon, ordered to Ft Lowell, Ariz.

First Lieut J D Porndexter, Asst Surgeon, ordered to Camp Poplar River, M T

First Lieut C N B Macauley, Asst Surgeon, ordered to Ft. Gibson, Ind Ter

Capt C B Byrne, Asst Surgeon, ordered to Washington Bks, D C

Capt T E Wilcox, Asst Surgeon, ordered to Ft Niobrara, Neb

Major H Lippincott, Surgeon, ordered to Ft Union, N M

Major P J A Cleary, Surgeon, ordered to Ft D A Russell, Wyo

Major D G Caldwell, Surgeon, ordered to Ft Assiniboine, M T

Capt G H Torney, Asst Surgeon, ordered to Ft Robinson, Neb

Capt Walter Reed, Asst Surgeon, ordered to Mt Vernon Bks, Ala

Capt J H Patzki, Asst Surgeon, ordered to Ft Huachuca, A T

Capt R G Ebert, Asst Surgeon, ordered to Ft Custer, M T

First Lieut J E Pilcher, Asst Surgeon, ordered to Ft Monroe, Va

Capt J de B W Gardiner, Asst Surgeon, ordered to Ft Washakie, Wyo Ter

First Lieut A R Chapin, Asst Surgeon, ordered to Newport Bks, Ky

Major W H Forwood, Surgeon, ordered to Ft Snelling, Minn

Capt H O Perley, Asst Surgeon, ordered to Ft Wayne, Mich S O 156, A G O, July 8 1887

S O 159, par 2, A G O, July 12, 1887, assigns Capt W Matthews, Asst Surgeon, as member of Army Retiring Board at Washington, D C, and relieves Capt J O Skinner, Asst Surgeon

Capts L M Maus and H O Perley, Asst Surgeons, ordered to accompany the Eleventh Infantry in changing station from Dept Dakota to Dept East S O 158, A G O, July 11, 1887

Capt E F Gardner, Asst Surgeon, ordered to accompany the Twelfth Infantry from Madison Bks to Duluth, and to return with Eleventh Infantry S O 143, Div Atlantic, July 13, 1887

Capt R G Ebert, Asst Surgeon, will, in changing station from Ft Hamilton, New York Harbor, to Ft Custer, Montana, accompany the Twelfth Infantry from Dept East to Dept of Dakota S O 159, A G O, July 12, 1887

First Lieut F V Walker, Asst Surgeon, granted leave of absence for four months S O 160, A G O, July 13, 1887

First Lieut Julian M Cahill, Asst Surgeon, ordered for duty as medical officer at Dept Rifle Camp, near Bellevue, Neb, August 1 next S O 66, Dept Platte, July 8, 1887

A board of medical officers, to consist of Major J S Billings, Surgeon, Capt W Matthews, Asst Surgeon, Capt F C Ainsworth, Asst Surgeon, is constituted to meet in this city for the examination of a candidate for admission to the Medical Corps of the Army S O 157, A G O, July 9, 1887

ADDRESSES

THE SYSTEMATIC TRAINING OF NURSERY-MAIDS

Abstract of the Third Annual Address to the Graduating Class of the Medical and Dental Departments of the National University, Washington, D C

BY SAMUEL S ADAMS, A M, M D,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN THE NATIONAL UNIVERSITY

The selection of a field in which you shall labor is not an easy task, so I may be pardoned for suggesting one It is a field in which neither your age nor your bachelorhood will be objectionable, and it is one in which the laity will be glad to assist you It is also one in which both branches of the class can take an active part for I believe all of you desire to benefit mankind

The field I propose for you is, so far as I am aware, a new one, but none the less wide and useful It is that of organizing a training school for nursery maids —that portion of our home guard which manages your patients during the periods of greatest sickness and mortality infancy and early childhood

That the management of children in general is wrong, unreasonable and unnatural is evident to any one who will consider the disproportion there is between the physical and mental capacities of the present generations, and diligently seek the causes We not infrequently meet in early life examples of unusual mental activity supported by a tottering physique, or in another case an early sacrifice of both mind and body By excluding transmitted vices of constitution, this impaired mental and physical condition is in my opinion largely due to bad nursing and bad habits contracted in early life As a method for the correction of the evils consequent upon the mismanagement of children I now ask you to consider the necessity for and desirability of the systematic training of nursery maids

In thus attempting to invade the sanctity of the nursery I trust that I may not be charged with trespass, as my sole object is to convince mothers of the importance of early training My ideas on this subject are not those of a doctrinaire but are the natural outgrowth of a decade's experience with children of different races and nationalities and of various stations in life from the highest to the lowest During this period the children that have passed under my care and observation have been in great part sick, but this has had but little weight in the formulation of my opinions I feel that an experience of eleven years, much of it with children in public and private practice, will certainly justify me in offering a few suggestions to young mothers as well as young doctors It may be said that it is unfair to judge of the early training of children from their manner, habits and conduct while sick I admit the force of this so far as the child is concerned, but when we witness the glaring defects of parental management which are so apparent in the sick room, we are justified in the conclusion that the like management in health cannot be what it should be For although the disposition of the child may be affected by disease the management of a sick child is a good exhibition of parental government

It is a sad commentary upon our boasted civilization that even educated women are not prepared for maternal cares, but are greatly dependent upon ignorant domestics for that knowledge of infantile responsibilities which should be learned in anticipation of maternity There is a kind of modesty pervading the female mind which seems to prohibit all reference to motherly cares by intelligent advisers This important duty has been too long left to uneducated women who are influenced by the examples and transmitted customs of their great grandmothers whose minds were warped by superstitious practices Indeed, so sacred are some of these superstitions that any attempt to convince an "old granny" that her methods are wrong will engender a prejudice against you that will have its effect beyond the nursery Nursing is gradually becoming more conformable to reason and common sense, though nurses still retain many traditional prejudices and, fancying that nature has endowed them with superior skill and wisdom, they often do much harm where they intended to do good If there is such a liability of young mothers being influenced by ignorant nurses to accept crude, barbarous and detrimental methods of nursery government, the importance of educating women for nursery maids would seem to be manifest It cannot be expected that a mother can properly superintend the mental and physical development of her offspring until she has studied the necessities of childhood, the characters of children, and the consequences of good or bad management It is in the nursery that many good and evil habits are formed If the evil are overlooked they may possibly be corrected later in life at the cost of much suffering and trouble, but it is much easier to prevent bad habits than cure them, hence it would seem more profitable to sow good seed in the garden and not leave

the soil barren, trusting to luck for good fruit It is no less true that the laborer in the nursery should be capable of distinguishing between traits of character which should be developed and those which should be eradicated

The education and early habits of nurses, and their training for the duty they are expected to perform, are sadly deficient It is necessary to have their services, therefore, they should be trained for the work In fact we complain of their bad qualities and ignorance, but seldom use any means to correct them I do not hope to eradicate this evil in the lower classes, but it can be modified by instructing the mind and appealing to the reason and the best feelings of human nature by means of example, precept, counsel and sympathy The gradual removal of these defects can best be accomplished by enlightening the understanding of those who are to have charge of the nursery

It is a rule in all professions that a person must have a general knowledge of the work before he can perform it, but this is not so in the management of the nursery We expect the watchmaker to understand the mechanism of a watch, the groom to be familiar with the peculiarities of the horse, the cook to be proficient in the mysteries of the kitchen, and the maid to know the latest style of dress making, hair dressing, and millinery, but we are willing to entrust the delicate mechanism of a child to one of whom rarely more is required than a good name, a little experience, an even temper, and a recommendation which is seldom investigated to see if it is genuine When mothers are convinced that something more than these few attributes are essential to a competent nursery-maid, we may hope to see the mental and physical health of our children improved

All children require moral and physical treatment, and whether they be rich or poor their physical being demands proper food, proper clothing, sleep, ventilation and exercise, while their moral training requires example, discretion, and cultivated senses and faoulties

In the higher walks of life a radical reformation in nursery government cannot be expected as long as the social duties of parents is such that the care of their children is consigned to a *supposed* competent maid hired to act as sponsor for their mental and physical growth upon no other justification than a neat appearance and a good recommendation from some unknown last employer

If I should ask a mother what she considered the duties of a good nurse to be, I venture to assert that she would reply to wash the child, dress it, feed it, put it to bed, take it up again, take it out for an airing, and not let it fall out of her arms Now if she should ask me to define her duties, I would say that she should be capable of giving proper attention to the bodily necessities of the child and like attention to the necessities of its mind

I do not pretend to have any novelties to offer, either in theory or practice, but only desire to define *what* the duties of a nursery maid are and *why* they are *her* duties, and *how* she can best be instructed as to their performance Her ignorance of the proper methods of nursing is a misfortune rather than a disgrace She should have the opportunity of being taught such methods by qualified instructors

The successful operation of the training school for sick-nurses has demonstrated the advantages of skilled nursing in the sick-room It has seemed to me of quite as great importance to establish a training school for nursery maids With the aid of the former we can undoubtedly manage disease better, with the aid of the latter we *may* fulfil the *higher* mission of preventing disease

In an examination of the vast amount of literature in the U S Army Medical Library, upon the nursing and management of children, I failed to find any reference to a training school for nursery-maids, so I may be the first to suggest such an institution Its value will seem more plausible when we consider the *natural* method of instructing children which has been so successful in our public schools The ease and rapidity with which children learn from *object teaching* will astonish the most sceptical

The school should embrace a corps of instructors whose duty should be to lecture upon various subjects appertaining to the nursing and management of children The requisites for admission should be a kindly, gentle disposition, a good moral character, a healthy constitution, a prescribed age, and a limited education They should be taught the dietary suitable for different ages, and *when* and *how* it should become more liberal, the various qualities of foods, and the best methods of preparing them, and generally their qualities in regard to digestion and assimilation

Another important subject to be taught in such a school would be the proper clothing for children, a field in which there is ample room for reform I hesitate to particularize lest in disentangling the limbs of the children I find myself the object of maternal indignation for thus rashly invading the peculiar province of feminine talent

A sleeping child is the picture of contentment The bright smiles flitting across its face indicate the pleasant dreams of health Sleep is its normal condition for most of its day and night, and if it does not sleep, it is because it has been overfed or is in a painful position, or has not had sufficient exercise, or is sick Your nursery-maids should be taught all this, and what the indications of the various causes of unsettled sleep are They should further be taught not to walk or rock the child to sleep, and instructed in the various methods of management, *especially in this regard*

They should be taught proper methods of open air exercise for children, the effect of atmosphere, of exercise, of sufficient and insufficient clothing, the dangers and consequences of exposure, and the necessity for constant and unremitting care and prudence when out for the daily airing

A few lectures upon the anatomy and physiology of childhood would prove beneficial in preventing the numerous injuries incident to rough handling, and in saving the child from the many troubles which are frequently the results of the violation of physiological laws

Another branch of instruction, and one of the most important, perhaps, should be in regard to the moral training of infants, for the influence of the nursery is great and very frequently continuous through life She should be instructed that the infant knows practically nothing until it has been taught, and that the best means of teaching is by sight, hearing, taste, smell and feeling As children learn largely by imitation, it follows that a good example, good manners and cleanly habits should be carefully taught as an important branch of the education of nursery maids, and among things she should be taught not to do, is the indulgence in deception, vulgar talk, ugly facial expressions, ungraceful attitudes, the use of "ghost stories" or thrilling narratives, and, in fact, the avoidance of all unseemly, indecorous and improper language and conduct in the nursery I have no doubt that many of my hearers have seen the consequences of some or all of these

Finally, to conclude this brief summary of what should be taught in the proposed school, I have left to the last what may be, perhaps, the most important —the necessity for studying the various peculiarities of disposition and character, and of moulding and modeling the child with reference to them

With this brief *resume* of the scheme of instruction to be pursued in the field proposed, I submit to you that if you will interest yourself in it, and by so doing succeed in correcting the numerous mistakes and errors now so common in the nursery, you will find that your earlier professional days will be pleasantly employed, and that you will not have labored in vain

---

ABSTRACT OF A LECTURE ON CHOLERA AND ITS TREATMENT[1]

BY PROFESSOR DR H VON ZIEMSSEN,
DIRECTOR OF THE MEDICAL CLINIC IN MUNICH

[The lecturer spoke of the importance of the subject, of its classification, the views of different students, as Pettenkofer and Koch, in regard to the nature of the infectious material, the duration of the cholera poison, and the ways of invasion He accepts Koch's views The incubation period varies between 12 hours and 5 days The clinical picture varies according to the intensity of the infection Cholera diarrhœa represents the mildest degree of the infection, beginning with dyspeptic troubles, or comes on suddenly without these, usually at night With painful gripings come on a number of copious, thin, light-colored discharges, usually painless and with a feeling of relief, but often with an unpleasant sensation in the abdomen, general malaise, pain in the head, and slight fever[2] During an epidemic of cholera these cases are of unusual frequency, too often ignored by unthinking persons, and by others magnified into more than their real import When properly treated they run the course of simple infectious intestinal catarrh, and health is restored in one or two weeks But if the diarrhœa be unchecked new infectious material gets into the intestine, and the simple mild diarrhœa develops into cholerine, or the asphyctic form of cholera

Cholerine, the specific infectious vomito diarrhœa, usually comes on suddenly at night, after dyspeptic troubles, diarrhœa and the development of gas in the intestine Vomiting and diarrhœa succeed each other rapidly, the discharges are abundant, fluid, feculent at first, but soon colorless, and very much like water There is moderate fever, small pulse, great thirst, rapid decline of vital force, sinking of the renal secretion, excessive muscular weakness, cramps in the legs, and partial loss of voice These symptoms are exactly those of cholera nostras, in which there are some fatal cases which take on the symptomatology of cholera asphyctica In favorable cases the normal function of the stomach and intestines is restored in one to two weeks, though there is great weakness which lasts for several weeks

Cholera asphyctica, cholera algida, begins with prodromal diarrhœa, which often seems harmless to the patient because it is generally painless and accompanied by a feeling of relief After a day or so of this diarrhœa the so called cholera attack begins, usually at night, the discharges suddenly become very copious, frequent, whey-like, and follow in rapid succession, and then follow the usual symptoms of true cholera In very severe cases the disease takes on a typhoid form, the most important symptom of which is the disturbance of the renal secretion, which may induce uræmia There are also cases of simple febrile reaction, without important organic affection, but with all the phenomena of high fever, and finally taking on a typhoid form through secondary affection of organs, in these cases diphtheria of the mucous membrane of the large intestine, the vagina, the urinary and gall bladder, of the throat and larynx play the principal rôle Rarely are there inflammations of the lungs, serous membranes etc

In regard to quarantine, sanitary cordons, etc, the author is in accord with the best sanitarians land quarantine is impracticable and impossible Cholera patients should not be brought into contact with other sick persons The details of individual prophylaxis include first the cleansing of the houses, the floors, and the surroundings, a regular healthy mode of living, which conforms as nearly as possible to the accustomed methods, and the especial avoidance of all food which may induce digestive troubles Those with weak digestive organs should exercise double care Especially to be warned against are unripe fruits, cucumbers, fat meat and insufficiently fermented beer No food should be taken unless it is well cooked, except such foods as are usually eaten raw, which should be previously washed with a disinfecting solution, such as a 1 20,000 solution of corrosive sublimate or a 1 1000 solution of salicylic acid, and then washed off with freshly boiled water Milk should always be boiled a short time before it is used, and water should be boiled, acidulated with hydrochloric acid and then cooled Of wines preference should be given to the red in case they have

[1] Translated by permission of author and publishers, from advance sheets by Wm G Eggleston M D of Chicago

[2] According to Poznansky the coming attack of cholera is indicated by slackening of the pulse and the disease may be thus diagnosticated in healthy people and the gravity of the attack is in direct proportion to the slackening of the pulse [*Trans*]

been bottled before the beginning of the epidemic After eating and drinking from 8 to 10 gtt of hydrochloric acid should always be taken, on account of the very noxious effect of this acid upon the comma bacillus Strict personal cleanliness, frequent changes of linen, sufficient clothing, and movements in the fresh air are necessary Cholera infected houses and quarters are to be avoided, and especially a room situated directly above one containing a cholera patient [3]

We now come to the treatment of the cholera patient The present therapy of cholera is based on the consideration that we have to do with a specific mycotic process in the mucous membrane of the small intestine, and that the exuberant culture of the comma bacillus here is the cause of the colossal transudation into the intestinal canal, and further, that a product arises from this fungous culture which poisons the whole organism in the most severe manner If this be correct—and it can scarcely be longer doubted—we have first to direct our attention to the bacillus culture in the intestine, and in the second place we must antagonize its action, guard against the blood thickening which is the result of the transudation, and against the motor paralysis, the result of the action of the alkaloids of decomposition of the bacilli It must therefore be apparent that the treatment is the more efficient the sooner it is begun So long as we have to do only with the prodromal diarrhœa we may hope that the drugs which we give will affect the bacillary process in the intestinal wall But if vomiting has set in it is very probable that nothing will reach the intestine from the stomach, or at least we cannot depend on the drug acting

In my experience calomel has the first place of all drugs which have been recommended in the prodromal stage After having tested its action in the beginning of typhoid fever I would now begin treatment in cases of cholera with 2 or 3 doses of 5 gram (gr vijss), and then give small doses of grm 05 (gr ¾) every two hours Calomel is superior to all other antimycotic drugs in that its action is tolerably clear, and its harmlessness in inflammatory infectious conditions of the intestines is sufficiently shown in the initial stage of typhoid fever We know that a part of the calomel is changed into corrosive sublimate in the intestine, how much we do not know, but the quantity of sublimate formed is sufficient to have an antimycotic action, for since a 1 30,000 solution of corrosive sublimate is instantly fatal to fungi we can easily understand the action of the smallest quantity of sublimate in the intestine For the same reasons subnitrate of bismuth is used by others in doses of gr vijss—xv several times a day, and pure resublimed napthalin is recommended for trial by Rossbach in doses of gr jss—vijss 5 to 10 times in 24 hours in keratin pills

I cannot join in the general praise of opium, I have seen more unfavorable than favorable effects from it, and it seems to me that the cases treated with opium take on more severe symptoms and character than those treated without it The same was said by Dornbluth of the Rostock epidemic of 1859, in which at last opium was entirely given up Whether in larger doses it would act otherwise and better than in the usual small doses I cannot say

The ethereal oils, as represented in the so called cholera drops, are thought to act favorably This "cholera drops" is a mixture of opii croc 6, vini ipecac 4, tinct valerian aeth 12, and ol menth pip 1 S 15 to 25 drops every half hour in peppermint tea These so called Russian drops are used with peppermint tea, more especially in the light diarrhœa and early pains of cholera In time of cholera they should be kept in every house, as their presence will serve to allay fears of a night attack Peppermint tea and the ethereal oils have an atrocious taste and increase nausea Good Russian tea with some rum is more pleasant to most people Mulled wine also (half a pint of red wine cooked with cinnamon, cloves and sugar) is exceedingly pleasant, and is to be preferred to hot grog on account of the ethereal oils which it contains, and also on account of the amount of tannin in the warm aqueous alcoholic solution

As regards diet and everything connected with it the physician cannot be too strict In time of cholera every case of diarrhœa must be at once put to bed, a warm dry covering placed over the abdomen (hot bran sacks, or a pot lid with flannel covering), and the patient given a cup of hot tea If there is indigestion it is advisable to give a hydrochloric acid mixture (3 to 150 water and 25 syrup), and for food and drink only oat and barley water should be given And this exhausts the most essential part of the treatment of cholera diarrhœa Since it can be diagnosticated from a simple catarrhal diarrhœa only by finding the comma bacillus in the discharges, and as the necessary bacteriologal examination of the stools is impracticable in the majority of cases, the safest plan is to regard all cases of diarrhœa, which is profuse and resists other remedies for 24 hours, as infectious, and treat them with calomel, and keep the patients in bed until the stools become normal

In cholerine, the specific infectious vomiting and diarrhœa this same method of treatment is most important, but in view of the profuse discharges, the severe nature of the attack and the vomiting, the antibacillary treatment must be kept in mind, and with the other treatment recommended 3 doses of calomel of 0 5 should be given in the course of 3 hours, and the calomel continued in small doses Of course we cannot know how much of this reaches the intestine It is not advisable to give other drugs, such as opium, as it will only be vomited For the vomiting, and to allay thirst small pieces of ice may be swallowed, and morphia may be given subcutaneously in doses of 01— 02 For the very profuse and obstinate diarrhœa the warm tannin injections as used by Cantani are best

There is no difficulty in making the diagnosis of cholera algida The attack sets in with such stormy symptoms, and the subsequent conditions develop so rapidly in a few hours that the diagnosis is certain as soon as the physician enters the room When first

[3] For rules for disinfecting clothing, bedding etc see Report of Committee on Disinfectants of the American Public Health Association, a *résumé* of which are given in THE JOURNAL, Vol VI, p 11 [*Trans*]

called to a case of cholera give 0 5 of calomel every hour for three hours, and then 05 every two hours While it is possible that none of the calomel will reach the intestine, but all may be vomited, and that the bacillus culture in the intestine has already reached a high grade, the calomel is recommended

Enteroclysis and hypodermoclysis, as used by Cantani and his Italian colleagues, should be made use of immediately [4] The earlier this is done the better the chances for recovery, according to Cantani It is absolutely necessary that the physician have the ingredients for these procedures, tannin in doses of 20 grams for the first, and 4 grams of sodium with 3 of carbonate of soda already mixed and ready for use He should also have a case containing a glass syringe of 25 or 50 ccm capacity (I use the same as for blood injections), several cannulas, and a horn cannula (hard rubber?) with a long rubber tube for the infusion A funnel can be had in almost every house, as well as boiling water If these things have to be got ready when needed one or two hours may be lost, which is serious both for the patient and physician

Enteroclysis is made by Cantani's method with 1 or 2 litres of a 1 per cent solution of tannin, at a temperature of 39° or 40° C , several times a day Of the value of the tannin infusion, which is used not merely in the prodromal diarrhœa but in the asphyctic stage also, Cantani says The warm mass of water certainly acts mechanically and by its heat in a way to vivify and stimulate the intestine and the whole organism, but the principal point is the stimulation of absorption, in consequence of which thickening of the blood and anuria are prevented, or actively antagonized if already set in In many of Cantani's cases the renal secretions again became active a few hours after enteroclysis Cantani thinks, furthermore, that the tannin sterilizes the contents of the intestine by souring, and perhaps at the same time forms very insoluble tannin compounds with the alkaloids of degeneration, thus rendering them harmless, and also limits the transudation from the mucous membrane by its astringent action on the blood vessels Cantani goes on the assumption that the infusion passes the ileo cæcal valve and enters the small intestine, sometimes even going into the stomach, as is shown by the fact that the tannin solution is sometimes vomited, or may be removed from the stomach by the stomach pump Cantani adds that hydrochloric acid used in a 5 per cent solution sterilizes more powerfully than tannic acid, but is less astringent, and that corrosive sublimate, salicylic acid, boracic acid, thymol, and other substances perhaps act still better than tannin, but his results with the last were so good that he made no other experiments There are several hypothetical assumptions in regard to this method, especially the washing out of the small intestine,[5] but the reports of the Italian physicians are so favorable that the value of this simple procedure cannot be doubted

The purpose of Cantani's hypodermoclysis is to antagonize the effect of the rapid loss of water and alkalies from the blood and tissues in a simple and harmless manner by the subcutaneous infusion of an alkaline saline solution The method is as follows From 1 to 1½ litre of a solution of sodium chloride 4 grams, sodium carbonate 3 grams, to 1000 ccm of water (Drs Boretta and Minola, of Naples, also add 3 grams of sodium sulphate) at a temperature between 37° and 40° C , according to the temperature of the patient, are injected into the subcutaneous tissue of the body by means of a somewhat complicated apparatus, after previous disinfection of the trocar The mass of water is left by Cantani to spontaneous absorption, which takes place more quickly if a soap bath at 40° C has just been given The infusion must be repeated about every four hours, until the favorable effects, which may even appear after one injection, are manifested These effects are re-animation of the organism, warming of the extremities, improvement in pulse and respiration, and disappearance of anuria and cyanosis [6]

In Italy the results seem to be very favorable generally, though Cantani's statistics have no value For in order that cholera statistics be of value there must be exact diagnosis of the form of disease and the stage of the disease, as well as a statement of the period of the epidemic in which the cases occur The prognosis of individual cases depends very much on the stage of the epidemic, with equal intensity of the disease the prognosis in the last stages of the epidemic is very much better than at the beginning But the method seems to have an undoubtedly favorable influence on the disease But I would advise that the method be much simplified The complicated injection apparatus of Cantani is entirely unnecessary A glass syringe of 50 ccm capacity, such as I use for subcutaneous blood injections, with 2 or three cannulas, is entirely sufficient I would further advise that the salt solution be dissipated by massage, as in case of blood injections, for absorption will thus be hastened, and in a quarter of an hour 1 or 1½ litre injected in 2 or 3 places can be easily dissipated and absorbed The physician can

[4] By Enteroclysis is meant the injection of a large quantity of fluid into the intestines Cantani used tannin solution Hypodermoclysis is the injection of a large amount of fluid into the subcutaneous cellular tissue For hypodermoclysis Cantani usually employed a solution composed of water 1 litre sodium chloride 4 grams sodium carbonate 3 grams This is heated to 39° or 40° C and injected Cantani says that the sides of the abdomen are the preferable sites for the injections The quantity of liquid to be injected should not exceed 1500 ccm as a rule when the patient is in the algid asphyctic state When the patient is not very dry smaller injections are better—from 800 to 1000 ccm at a time In the typhoid stage the injections should be of 500-600 ccm each In most cases it is necessary to repeat the subcutaneous injections until the pulse reappears or increases in strength the respiration improves cyanosis lessens and urine is secreted The hypodermatic injections should be still more frequently repeated in the typhoid state The more advanced the symptoms of algidity and paralysis the higher should be the temperature of the fluid injected (39° or 40° C) Cantani says that the practical results of enteroclysis in cholera were even more splendid than those of hypodermoclysis

Vincenzo Vitone used successfully the following solution for enteroclysis warm water 100 grams tannic acid 3 grams gum arabic 20 grams laudanum gtt 12 in a child of 8 years E Vilcani has used as much as 15 grams of tannic acid to 2 litres of water

Cantani's solution varied from a 1 per cent solution of tannic acid to 2 grams 600 ccm

For abstract of Cantani s article see Lancet Sept. 26 and Oct 3 1885 [*Trans*]

[5] There is no doubt that fluids can be thrown *per rectum* beyond the ileo cæcal valve [*Trans*]

[6] M Hageur during the recent epidemic in France treated cholera by venous injections of saline solution To a litre of distilled water was added 10 grams of sodium chloride and 8 grams sodium sulphate heated to 38° C The injection was effected in from 12—15 minutes In the case of all feeble subjects this treatment produced only incomplete reaction when the algid condition had been pronounced Among healthy sober adults and children the results were remarkable the injections seemed to rescue them from certain death [*Trans*]

easily carry the syringe recommended, as well as powdered tannin, salt and carbonate of soda, which are to be dissolved in thoroughly boiled water The needle should also be thoroughly boiled before each injection

I may also mention here the procedure of Keppler, which he has used with good results in Venice For the subcutaneous injections he uses a solution of 7 grams of salt, 1000 ccm of distilled water, and 10 grams of absolute alcohol This solution is warmed to blood-temperature, and injected into the neck or infra clavicular region, 50 ccm being injected every minute until the pulse returns, then every 5 minutes, and later every half hour In all, from 8 to 12 litres are used Keppler emphasizes the great value of the alcohol for sustaining the heart, and especially commends the value of the method when used early The advisability of adding alcohol to the solution is apparent, and should not be neglected

The subcutaneous method is certainly the most promising, and capable of many modifications, especially as regards the use of antimycotic and other drugs On account of the danger in which the patient is, and the anxiety of his friends, other measures than those mentioned must be resorted to Of these stimulants are of the first importance [7]

In beginning paralysis and cyanosis camphor, in the form of ol camphorat fortius (1 5 instead of the officinal 1 9) should be given, preferably hypodermatically, and when from 3 to 5 syringefuls are injected one after another at the right time the action of it on the heart is very favorable In many cases everything depends on energetic stimulation, and for this camphor is much superior to ether, in that there are no local after effects from its use, such as suppuration and gangrene Stimulants which act through the stomach, such as the preparations of alcohol, have no especial value, for the stomach will absorb nothing, and at most the mucous membrane of the fauces and œsophagus will take up but little Champagne is to be recommended, placed on ice, with broken ice in it, and taken in small quantities, this is very grateful to the patient

In the muscular cramps of the legs and other parts it has always seemed to me that rubbing the bellies of the muscles with large pieces of ice was the best remedy Spiritus saponis is also used for rubbing, but when much used acts unpleasantly on the olfactories of the patient and attendants

Continuance and repetition of diarrhœa with colic and tenesmus are best treated locally with warm infusions of tannin with the addition of some opium, or, if large infusions are no longer borne, by means of small clysters of warm thin starch and opium injections (starch decoction 30 grams, with gtt 20 tinct Thebaic), repeated several times a day In the later stages of the disease, when the condition of infection and intoxication is broken and the resulting local disturbances become more prominent opium is very useful

Cholera typhoid is treated symptomatically according to the more prominent disturbances The uræmic form, as in cases of acute scarlatinal nephritis, is treated with warm, and in lowered temperature with hot, baths, followed by warm woolen coverings, and internally with milk in large quantities mixed with carbonated waters Drugs are practically useless, and so called diuretics do more harm than good

The diphtheritic as well as the inflammatory (pneumonic, etc) forms of cholera typhoid are treated according to the established rules for these diseases, though it must be remembered that here we have to do with an organism which has been severely poisoned, and whose organs are more or less crippled The cautious use of food and stimulants will therefore play a leading part in treating the local affection

The diet of the convalescent cholera patient demands especial care The severe and partly necrotic lesions of the intestinal mucous membrane, the extensive epithelial loss, the tendency of the vessels to new hyperæmia, the faulty state of the assimilative functions, all demand the greatest precaution, and we cannot too strongly oppose the impatience of the patient and his friends to quickly return to solid food and to leave the bed Restoration takes place more rapidly and more completely in bed and on a fluid and semi fluid diet You will not go wrong if you regulate the diet for three or four weeks as you would after a severe attack of typhoid fever I would recommend the following diet Night and morning, tea with English biscuit, Noon, meat broth and meat juice, a soft-boiled egg, with a little Port or Marsala, some minced lean ham, or pigeon or chicken, or partridge in the broth, light red wine, such as Bordeaux, Voeslau or Ofen, slightly warmed, Afternoon, tea with cakes Supper, mucilaginous soup with meat juice, meat extract and wheat-bread, and half a pint of well fermented beer After this we may allow boiled rice or grits with blackberry juice Thickened blackberry juice (strained) is very advisable on account of the quantity of tannin which it contains, made into a compote it is very digestible Bilberries (blueberry, whortleberry) may be allowed after having been soaked in fresh water for 24 hours, when they swell up as though just boiled The only drugs to be used at this stage are bitters, both pure bitters for the improvement of the appetite and of the gastric functions, and the combined for their influence on intestinal digestion and on peristalsis, of these radix rhei is best Irregularity of the bowels is so very frequent in the course of convalescence from cholera that the patient cannot do without rhubarb In small doses, in which the bitter principle acts more than the cathartic acid, it obviates the fatal tendency to diarrhœa and flatulence, while in larger doses it acts well in case of existing constipation In the first case I would recommend the aqueous tincture of rhubarb with elixir aurant comp in equal quantities, giving a teaspoonful two or three times a day If stronger action be needed the tinct rhei vinosa either pure or with elix aurant comp and tinct chinæ comp may be given in teaspoonful doses

After convalescence is established I would recommend salt baths in a mild mountain climate, and in winter a climatic resort (sanitarium)

[7] Poznansky recommends small doses of hydrocyanic acid given at intervals, which quicken respiration, make the circulation more active, and raise the temperature [*Trans*]

ORIGINAL ARTICLES.

INTUBATION OF THE LARYNX, WITH INFERENCES FROM ONE HUNDRED AND THIRTY-FOUR OPERATIONS

Read in the Section on Diseases of Children, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY J E WAXHAM, M D,

PROFESSOR OF DISEASES OF CHILDREN COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO PROFESSOR OF LARYNGOLOGY AND RHINOLOGY, CHICAGO OPHTHALMIC COLLLGE

In presenting this paper, it is not with the object of instructing this assembly or of imparting anything new or startling, but simply to present the result of my experience with this new operation, with which you are all familiar, and to excite a discussion which will be more valuable than any contribution

On April 19, 1885, I performed intubation, for the first time, according to the method of Dr O'Dwyer In August, 1886, I reported 83 cases with 23 recoveries, or a percentage of 27 71 Since the latter report it has been my privilege to perform the operation in 53 cases, with 14 recoveries, making a total of 136 cases with 37 recoveries, or 27 20 per cent

The ages of these patients were as follows

5 cases with	1 recovery	or 20 per cent	under one year	
15	3 recoveries	or 20	between 1 and 2 years	
29 "	7 "	24 "	2 "	
23 "	4 "	21 "	3 "	
21 "	7 "	33 "	4 "	
15 "	7 "	46 "	5 "	
3 "	1 "	33 "	6 "	
9 "	2 "	22 "	7 "	
4 "	2 "	50 "	8 "	
2 "	2 "	100 "	9 "	
2 "	0 "	00 "	11 "	
1 "	0 "	00 "	14 "	
7 "	0 "	00 "		
136	37	27 20	Average 3 yrs 8 mos	

There were 72 cases three years old or under, with 16 recoveries, or 22 per cent, while there were 64 cases over three years, with 21 recoveries, or 32 8 per cent

The youngest patient to recover was an infant of nine months, the oldest a child of nine years In every case without exception false membrane was observed The longest period that the tube was worn was two weeks, the child being but two years old and making a perfect recovery The shortest period that the tube was worn was one hour The patient was a boy three years old, and was under the care of Dr J G Berry The patient was in a semi comatose condition and was almost pulseless All who saw the child were firm in the belief that he could live but a very short time The tube was introduced and the child was soon resuscitated, considerable membrane being rejected In an hour we were again called in great haste, as the child had coughed up the tube, together with a small piece of membrane As the respiration was perfectly easy the tube was not reintroduced The membrane did not re form, and the child made a rapid recovery

Taking the above cases as a standard, the results would seem satisfactory

In the whole history of tracheotomy where can we find a record of 72 cases of three years or under, with recoveries amounting to 22 per cent ? Indeed, tracheotomy is so rarely successful at this age that many consider it a contraindication to the operation After the age of three years we have a record of 64 cases with 21 recoveries, or 32 per cent A record certainly comparing favorably with tracheotomy

Many, in criticising intubation, speak slightingly of the operation and insinuate that the operation is *always performed early* and often unnecessarily. Such is not the case In my own experience the operation has often been delayed and accepted only as a last resource It has not been performed until there has been absolutely no hope without surgical interference

Many, with limited experience, report a much higher percentage of recoveries than has been given above Some report as high as 30, 40, and even 50 per cent of recoveries In my own experience 17 successive operations were followed by 8 recoveries, or 47 per cent In another series of cases 13 successive operations were followed by 6 recoveries, or 46 per cent Taking a large number of cases, however, of all ages, conditions, and grades of severity, and we can hardly hope to save more than about 25 per cent This, however, is a larger proportion than can be saved by the majority of physicians with tracheotomy

DISCUSSION

DR A B STRONG, of Chicago, said We have listened to a very favorable report on intubation of the larynx for diphtheritic croup The report is, I am firmly convinced, much more flattering than the facts would warrant, had each and every case so far intubed been appealed to It is but natural that we should first hear everything favorable to this operation, and but little against it Surgeons are not accustomed to report their failures or mistakes, yet failures, and many of them to one success, are legion It is time that the other side should be heard from For one year prior to last February I gave the subject of intubation for diphtheritic croup much study and most careful practical attention During that time I intubed 32 cases, and 31 of them are dead With these personal facts before me, I certainly am no longer justified in recommending the operation Since then I have refused to intube a large number of cases I deem it my imperative duty to the profession, and in the interest of humanity, to give you the benefit of my experience The operation, when skilfully done, is easily and quickly performed, without blood, anæsthesia, or fright of parents With one or two exceptions I have had no trouble whatever to introduce the tube in a few seconds The first result, relief of the dyspnœa, is all that could be desired, for a few hours everything as a rule has gone on nicely But look at the ultimate results! Thirty one dead, either from the extension of the membrane downwards, traumatic bronchitis, or pneumonia, or both combined, or from actual starvation. The trouble was the children could not eat or drink without in each case and every attempt some of the contents of the mouth passing through the tube into the air passages, and so exciting them to resentment

or inflammation To inject a little food into the rectum of a child is easy enough, but as a means of nutrition it is practically a failure To put a rubber catheter through the mouth or nose into the stomach, can be done, though not easily or without great resistance from the frightened child To nourish the little one in this way, many times in the twenty-four hours, is, to say the least, of doubtful utility In bed side practice it is thoroughly impracticable

Again, in introducing the tube there is danger of making a false passage I know of three or four such cases, one of them in my own practice The point of the tube was seen and felt under the skin just above the hyoide bone On introducing the tube no force whatever should be used, unless you are absolutely certain that the point of the tube is in the glottis, and then only a minimum amount To avoid such danger knowledge, skill, and gentle manipulation are as essential here, or rather more so, than to introduce a sound into a narrow and tortuous urethral track without doing violence to the parts Don't make a false passage Don't use force

Again, when the membrane has existed in the larynx for three or four days, when it generally begins to loosen, there is great danger of crowding it down, with imminent risk of suffocating the patient This has happened to me four or five times Though there was no death from this cause alone, I came very near killing one little patient In short, my experience, personal and otherwise, on introducing the tube compels me to say it is not the simplest operation in all surgery To remove the tube is more difficult than to introduce it In about one fourth of my cases I have had more or less trouble to get the tube out That is, I failed on the first or second trial To get into the small hole at the upper end of the tube with the point of the extractor, while the larynx moves up and down and the child struggles, is easy to talk about, but to do it without puncturing the soft parts adjacent to the collar, or grasping them in the bite of the instrument, is entirely another matter In one of my cases the tube appropriate for the age slipped through the larynx It was not pushed through I had great difficulty in extracting it through the glottis It is scarcely necessary to say the child died a few hours afterwards from a then existing pneumonia and shock consequent upon the operation In only one of my cases was the tube coughed up I always found the tube perfectly clear, no incrustations This was so whether the tube had been in position a few hours or several days

I have heard enthusiastic supporters of intubation say that the after-treatment of a case wearing the laryngeal tube, was easy in comparison with a similar case wearing the tracheotomy tube This certainly has not been my experience I believe it to be a most erroneous claim Facts that I have observed will not sustain it The child is tormented with thirst, only when this great craving becomes intolerable will the little one eagerly attempt to swallow fluids He makes a bold attempt, gulps or sips down a little, but pays most dearly for his experiment in the distressing cough the act has excited You can't coax him to try that again until his burning thirst is so intolerable that he must have fluids Ice in the mouth serves him the same way He takes nothing willingly This is no fancy picture It is simply a statement of facts as observed in each one of my thirty two cases Some have not so much difficulty as others, but all have more or less, enough to do them a positive injury It makes no difference when the child is taking fluids, whether it is lying down or sitting up, head bent to one side or the other, chin depressed on the chest or occiput thrown back In any and all positions of the head, he can't drink without a dangerous amount of the fluid passing into the air passages

Since quitting intubation I have made tracheotomy in some cases, two of these recovered, making for me a total of five recoveries in eighteen tracheotomies Never before my experience with intubation did I fully realize what a great blessing it is for a child, after tracheotomy, to be able to drink as fully and as often as it desired without endangering its life by coughing or having its lungs irritated by the fluid I believe my personal experience warrants the assertion that tracheotomy will save every case that intubation will, and do it with much more comfort to the little patient and far less anxiety to the surgeon and parents

In conclusion, I would say there is one condition in which I have found intubation of decided practical value That is as aid to the after-treatment of tracheotomy You are aware that tracheotomy tubes sometimes have to be worn weeks and months after the patient has recovered from the laryngeal stenosis The text-books of current literature are full of such cases The explanation has been that granulations grow in the upper angle of the tracheal wound and so obstruct its lumen when the tube is removed that air cannot pass through the larynx

Surgeons have cut and burned off these growths once, twice, or it may be a dozen times, and still often they dare not leave out the tube for fear of suffocating the patient The trouble I have found is not so much in the granulations as in the obstruction caused by the infolding of the cut edge of a ring or two of the trachea, at the upper angle of the incision into it When the tracheal tube has been worn for days this infolding is well marked, together with depressed condition of a whole ring or two of the trachea just above this highest incised one This condition was most beautifully shown in one of my cases I tried many times for three weeks, by snipping and burning, to get rid of the tube Not till I placed the child in a good light and made careful examination of the part did I discover what was the matter I found abundance of granulations, but they were resting on the incurvated parts, as I have mentioned I introduced the laryngeal tube through the mouth and had the great satisfaction of seeing the infolding parts brought up to their natural position, and so the obstruction was removed I immediately removed the laryngeal tube and did not replace the tracheal one, and the wound healed quickly without any further trouble

The same experience I had with another case I

shall keep my intubation set for just such cases I shall not intube the larynx again till some modification of the O'Dwyer tube enables the child to swallow nourishment Some one else, however, will have to do the experimentation first No more of it for me

Dr M P Hatfield, of Chicago, said

My experience with intubation, although much less, closely resembles that of Dr Strong The cases were ten in number, the insertion of the tubes in the first two being performed by Dr Waxham, and the results were ten deaths In four of the cases death apparently resulted from exhaustion, or diphtheritic poisoning, in the remainder from "Schluck pneumonia," or that produced by food entering the trachea Consequently, I believe with Dr Tascher that the most valid objection against intubation is the dropping of food into the bronchial tubes and the resulting broncho pneumonia. This ordinarily appears in the course of forty eight hours, and is, and will continue to be, I fear, the most frequent cause of death after intubation The insertion of the tube, even in the hands of experts, is not as easy as they would seem to imply, but this difficulty can be overcome more easily than the danger just alluded to The tube often gives great, if not permanent, relief, but the more promising cases are the very ones in which the subsequent pneumonia appears At least, such is my experience It will be, I fear, that of the general practitioner who hopes to realize Dr Waxham's gratifying percentage of recoveries

Furthermore, it ought to be remembered that, while great credit is due to Dr O'Dwyer for his patient and conscientious experimentation with intubation, it is not a new device It was fully and fairly tried more than thirty years ago in France, and abandoned because the results were less favorable than those from tracheotomy In fact, Bouchut, who proposed the instrument, finally abandoned it entirely because, in his own words "The application of the cannula produces the results which might have been expected from an instrument of that nature It delays asphyxia and avoids a grave operation, tracheotomy, which the progress of events might have rendered useless " Does intubation do more to day?

Dr Mary Thompson, of Chicago I would like to ask Dr Waxham whether he introduces the tube in the original way—anteriorly or posteriorly?

Dr C W Earle, of Chicago I wish to compliment Dr Waxham for the introduction or revival of this operation in our city, and the skill with which he performs it I think we, as a profession, and those more particularly engaged in the practice of diseases of children, are under great obligations to him for pushing this matter forward The tabulated statement of cases which the doctor has presented to us this afternoon is very favorable indeed, although I think he is mistaken in believing that tracheotomy, in the hands of skilful operators, has not presented as good results I am in favor of the operation when I can get Dr Waxham to perform it for me The trouble is that everybody thinks he can do it It is like abdominal surgery—everybody believes he should be permitted to dabble in it, and many who have had no special study, practice or fitness, rush in to tube the larynx A large number of people will permit the operation of intubation who would not permit tracheotomy, and in my judgment many lives will be saved for this one reason There are a certain number of throats to be opened, for we shall always have cases of laryngeal stenosis, and tracheotomy or tubage must be done What we should insist upon is that only those specially fitted should be allowed to do this operation

Dr Waxham has undoubtedly saved more cases by intubation than any surgeon in the city has by tracheotomy, but if we knew all the unsuccessful cases which have taken place, the percentage would be small enough, and might not compare favorably with tracheotomy

Some operators in this city have tubed the larynx many times and have lost every case, and they are now crying a halt for the operation It is time for them to stop, or do as I do, send for Dr Waxham I have tried to do the operation with the doctor by my side it was impossible for me to enter the larynx, but as soon as I relinquished the instruments to my colleague the child was relieved at once I made this open confession before the Chicago Medical Society some weeks ago, and a quiet smile passed around the hall If others had made this same confession and stopped operating (and among them some who perhaps smiled), it would have been better for the babies I regard the operation as a justifiable one, and one which will save many, but I shall insist, as far as I am personally concerned, that none except those who are expert, those who have had a great deal of experience, and who thoroughly understand the technique of the operation, shall perform it I desire to raise my voice against every person getting a set of these instruments which the doctor has exhibited, and every time he sees a child suffering with slight stenosis of the larynx, attempting to do this operation I know a great many children are killed through lack of skill on the part of the operators The only criticism that I desire to make, and I have made it before, is that Dr Waxham represents that the operation can be done *with perfect ease by anybody* I think that in this he is in error *He* performs it easily, but everybody cannot

Dr J A Larrabee, of Somerville, Ky I regret coming in too late to hear the whole of the paper The statistical showing is exceedingly rare, and Dr Earle has more than covered the ground when he says that the great success is due to the skill of the operator. I have never performed intubation I think there is but one physician in the city of Louisville who has performed it, and in every case the patients died In three instances the tube was buried with the patient

We have had this past winter an epidemic of diphtheria in our city, and in the moribund cases in which I was called upon to do the operation of tracheotomy, under the most unfavorable circumstances, as a *dernier ressort*, I operated fifteen times, with three recoveries, the three patients that recovered were all under 3 years of age, and the others 4

Dr Waxham, in closing the discussion, said I am very glad to have heard from Dr Strong and from Dr Hatfield, for it is only fair and right that we

should hear from both sides of every question Because some have met with unvarying failure with tracheotomy, shall we denounce the operation? Because two or three have been unfortunate in their experience with intubation, shall we all vote the operation a failure? What do these gentlemen say when the statement is made that one operator has performed tracheotomy 100 times with but 1 success, and another 50 times with but 2 recoveries, another 20 times without a single recovery, and another 16 times with but 1 success, and still another 14 times without a recovery, making 200 cases by five operators with but 4 recoveries, or only one out of every 50? The failure of these gentlemen with intubation has more than its parallel in the history of tracheotomy, and I cannot understand why they should denounce one operation, and still uphold the other Indeed, I cannot understand the reason of their failure, unless it be from the use of too large a tube, or from lack of careful attention in the management of their cases I am not alone in my success Dr O'Dwyer reports to me 25 per cent of recoveries, while Dr Ingals, at the meeting of the American Laryngological Association, reported 514 cases collected from various sources with 134 recoveries, or 26 per cent, a percentage almost identical with my own

If you have intended purchasing these instruments, by all means do so, learn to use them *skilfully* and *well*, and I assure you that you will never regret it Do not be discouraged by the report of a few unsuccessful cases I feel that if any operation was ever a Godsend to suffering humanity, this one certainly is

In answer to Dr Thompson's question, I would say that I still introduce the tube with the beveled surface forwards, and the projecting shoulder backwards The epiglottis can more perfectly close the larynx with the tube in this position, and there is much less danger of ulceration

In answer to another question I would say that, while the artificial epiglottis does not work quite as perfectly in the larynx as it does under my finger, yet it is of great assistance in swallowing

There are many advantages that intubation possesses over tracheotomy, the chief one being our ability to gain the consent of the parents We shall have a great many patients where tracheotomy would not be allowed One of the most touching incidents of my life occurred not long since I was called to perform the operation upon an interesting child of 4 years The people would never consent to tracheotomy, and the mother left the room weeping and in the deepest distress at the thought of having even this operation performed upon her child The nurse took the suffocating child upon her lap, and in about five seconds the tube was in position and the child perfectly relieved The mother was recalled, and approaching the child, crying and wringing her hands in the greatest grief, the little one looked up to her with a smile, and said, "Mamma, I never said boo!" This certainly is a great contrast to the scene at a tracheotomy But we must have other than æsthetic reasons for preferring intubation to tracheotomy The crucial test is this Can we save as many or more lives by this method than by tracheotomy? The statistics bear me out in the statement that we can

I have now under my care a little patient 9 years old who has been wearing a tube for two days[1] The case was one of pharyngeal diphtheria, with extension of membrane in the larynx There are two other cases of diphtheria in the family The operation was performed to prevent impending suffocation, which had been increasing for two days I would suggest that a committee of two be appointed to visit and examine this patient and report their conclusions through THE JOURNAL of the Association

REPORT OF THE COMMITTEE ON INTUBATION

TO THE CHAIRMAN AND MEMBERS OF THE SECTION ON DISEASES OF CHILDREN, AMERICAN MEDICAL ASSOCIATION, 1887

Gentlemen —In accord with the provisions of the motion passed by your Section on the afternoon of June 9, 1887—a motion which directed the selection of two members of the Section to visit with Prof F E Waxham a patient upon whom he had performed the operation of intubation three days before, we the undersigned, your committee, visited the patient about 8 30 P M June 9 We found a girl, Minnie Smalley, aged 9 years, a light brunette, in the ninth day of an attack of diphtheria. Both parents, nurse and attending physicians, reported the child on the sixth day of her illness as apparently dying from dyspnœa She was cyanotic, with thready pulse, and there were little hopes of her recovery when Dr Waxham was called, and in a few moments succeeded in introducing a tube into the larynx with complete relief to all the threatening symptoms A spray of diluted alcohol was ordered, or rather was permitted, and semi solid foods directed Dr Waxham had not seen the patient again until the hour he called with your committee We found the respiration perfectly easy, 28 to the minute, not noisy, an easy cough with muco pus expectoration, voice a little hoarse and bronchial, lips red, skin dry, circulation good, pulse 125, soft, compressible, volume medium, temperature 101¼°, tongue coated with a white fur membrane still visible over arches and columnæ, but very thin and soft, adjacent parts red and inflamed While we were present the child ate tapioca pudding freely without any cough or spasm whatever She had not known there was anything in her throat until the day previous when her mother incidentally mentioned the fact The improvement had been steady from the moment the tube had been introduced

There were two other children sick with the disease in an adjoining room, but both cases mild Dr Waxham suggested a little more nourishing grade of food, and announced that he would remove the tube the following day, as it was a rule with him not to leave it longer than the fourth day, even if he was required to reintroduce within a few hours, giving as a reason the liability to the development of ulcerative action, and the danger in such case of the sloughing of the unhealthy tissues with the added complications resulting from such possibilities

[1] June 16—Patient fully recovered

It was the privilege of one member of your committee to be present next day, June 10th about 11 30 A M, and witness the removal of the tube, which was done in the exact manner advised by Dr Waxham in his monogram upon intubation The removal was accomplished with an ease, a dexterity and a skill which was a revelation to those present, a revelation which exhibited the hand and the mind of the master in his chosen art

Still clinging to the removed tube were pieces of false membrane from an eighth to a fourth of an inch in diameter, and as thick and firm as good strong blotting paper The child said she felt no pain, nor special annoyance during the removal of the tube, and a few moments afterward ate freely of some semi solid food Her condition was about the same as on the previous evening with perhaps a slight increase of debility and a tendency to heart failure, but still with many favorable symptoms giving strong hopes of recovery

On the 14th inst, *i e*, on the fourteeth day also of the disease, we received from Dr Waxham the following note dated the 12th inst "It gives me great pleasure to report that our little patient is now out of danger The doctor informs me that the pulse to day is 80, temperature down, strength improving, and that he considers that there is no further danger "

This adds one more success to the operation, and we assure you it adds two earnest converts to the importance and high value of the operation as a means of tiding over the most dangerous period in a certain proportion of cases of laryngeal obstruction in pseudo membraneous disorders Of course it requires thorough anatomical knowledge, manual dexterity, sound judgment, and well planned collateral management, but so does every other great success in hours of extreme danger

We believe that every gentleman who provides himself with the necessary instruments should also further prepare himself by repeated operations upon the cadaver until he has acquired the necessary skill to do the operation with rapidity and ease, thus adding largely to the possibilities of its success The celerity with which the operation may be performed, its freedom from local injury to the diseased tissues and its promptness in relieving a threatening fatal symptom, all commend its favorable consideration, and generally its preferable selection as compared with the older and possibly (?) more brilliant operation of tracheotomy

We believe that Dr Waxham deserves the thanks of the profession for his untiring and persistent efforts in giving this operation, with which his name will be always associated, the consideration it deserves, and in placing it in the high position to which it belongs in the list of remedial measures in desperate emergencies

(Signed,) GEO WHEELER JONES, M D

SUPPURATIVE INFLAMMATION OF THE ANTRUM

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association,

BY E FLETCHER INGALS, A M, M D,

PROFESSOR OF LARYNGOLOGY RUSH MEDICAL COLLEGE PROFESSOR OF DISEASES OF THE THROAT AND CHEST, WOMAN'S MEDICAL COLLEGE CHICAGO

The mucous membrane lining the antrum of Highmore is liable to suppurative inflammation and a collection of pus which may partially or completely fill the cavity, if its opening into the middle meatus of the nasal cavity remains patent, but when the latter becomes closed by inflammation and swelling of the Schneiderian membrane, the pressure caused by the continued formation of pus may cause great expansion of the bony walls, and corresponding increase in the size of the cavity This condition has been termed abscess of the antrum, but as, excepting the presence of pus, it is usually devoid of all the characteristics of an abscess of the soft tissues the term suppurative inflammation is more appropriate

From the location of the antrum, immediately above the bicuspid and molar teeth, the fangs of which often perforate its floor, and from its more or less free communication with the nasal cavity, it would be expected that disease of its lining membrane would be frequent, resulting either from affections of the teeth, or extending from the nasal mucous membrane, which is so often inflamed As a matter of fact, however, this disease cannot be considered common, for many physicians practice a lifetime without meeting examples of the kind However, it is doubtless more frequent than generally supposed, for it not infrequently happens that the affection is simply called catarrh, and its real nature is overlooked for want of a careful examination Inflammations in this locality are occasionally caused by external injury, and they are sometimes due to extension of the same process from the nasal cavity, but by far the most frequent cause is disease of the teeth The normal opening from this cavity into the middle meatus varies from the size of a crow quill to an opening nearly large enough to admit the tip of the little finger, in the latter condition the products of inflammation may be readily discharged, and a spontaneous cure may result without suppuration, but when the orifice is small it may readily become closed and then the pent up secretions become purulent and offensive In the earlier part of the affection the patient is liable to experience a sense of weight in the part, or to suffer from more or less tenderness and pain in the teeth, cheek, orbit or frontal sinuses, but in some instances none of these symptoms are present, and in chronic cases they are often absent, doubtless on account of the secretions having found free exit into the nasal cavity, as the swelling of the acute inflammation subsided

The formation of pus is usually indicated by an increase of the pain, which becomes of a throbbing character, and these symptoms are often attended by rigors alternating with flashes of heat Together with these symptoms an unusual discharge is usually

present from the naris of the corresponding side, which may be either blown from the nostril or drawn back into the throat This discharge is most abundant early in the morning, or at any time after the patient has been long in a recumbent posture, but it usually occurs also at irregular intervals during the day

In chronic cases the discharge is purulent and generally exceedingly offensive—much of the annoyance which the patient experiences being due to the offensive odor and taste of the pus which trickles in to the throat during sleep

Persistent discharge, from one nostril only, is usually due either to a foreign body, or to the disease under consideration, but nasal polypi, suppurative inflammation of the ethmoidal or frontal sinuses and polypi, or malignant growths of the antrum, may cause similar symptoms

Where pain in the region of the antrum and an offensive purulent discharge from the naris of the corresponding side are present, there can be little doubt about the diagnosis, but in all cases careful inspection of the mouth and a critical rhinoscopic examination must be made Upon examining the naris a collection of pus will often be seen in the middle meatus, and a streak of pus may be seen running down across the middle portion of the middle turbinated body If this is wiped away it is apt to return in a few minutes But in cases in which secretion takes place slowly, the patient may need to keep the head erect for many hours, and then lie down with the diseased side uppermost before the discharge will return

In many cases the inferior turbinated body is much swollen, so that it is at first difficult to thoroughly inspect the parts, but by the application of a small amount of cocaine the turgescence will be reduced, and then with the aid of a rhinoscopic speculum, reflector, and good light, foreign bodies or polypi may be readily detected or excluded from the problem of diagnosis This done, there remains but one affection with which disease of the antrum is liable to be confounded, viz suppurative inflammation of the ethmoidal cells Between these affections the diagnosis is sometimes exceedingly difficult, but in disease of the ethmoidal cells there is usually much less pain than in disease of the antrum, the discharge from the nose is less abundant, and on inspection the pus is found to trickle down at the posterior end of the inferior turbinated body instead of across its middle It will be remembered, however, *that in some cases of disease of the antrum* there is little or no pain, and that in others there is little *or no* discharge In cases of this variety the most important points in the diagnosis of suppurative inflammation of the autrum are

1 If there is no discharge there is likely to be much pain from the pent up secretions

2 Disease about the roots of the teeth is apt to be present, and

3 The history will often point to the origin of the disease

In a case with only moderate discharge and no pain, or history of an acute attack, the absence of diseased teeth and the position of the pus far back in the nasal cavity would point to disease of the ethmoid cells instead of the cavity of the antrum

Polypi, or malignant growths of the antrum, can only be detected when they have protruded, or when the cavity has been opened

The progress of the disease is usually slow, unless appropriate treatment be adopted When the opening into the naris is completely closed the patient suffers severe and exhausting pain, the pent up secretions cause gradual distension of the walls of the cavity, which may encroach upon the orbit, nasal cavity or palate, or which may cause marked bulging and deformity of the cheek If left to itself the cavity may open in any of these directions In some instances the putrid secretions that are swallowed cause serious derangement of the digestive organs and a gradual decline in health

In acute inflammation of the antrum medical treatment by fomentations, local blood letting, and salines, is important, but when suppuration has taken place surgical measures must be adopted Free exit must be given to the pus, preferably through the alveolar process When a diseased tooth is found to be the cause, it should be extracted and the opening left by its fang enlarged sufficiently to allow free drainage Sometimes the abscess points just above the teeth at the alveolar process, and then may be opened in that position, but this is not a favorable point for the opening on account of the difficulty of keeping it patent

If the teeth are sound it is best to draw the first molar, as its sockets are deeper than those of others, and it is the most liable to decay, but if the patient has already lost one of the upper bicuspids or molars the antrum may be entered through the space left It has been objected to selecting this spot that the bone where a tooth has been lost some time previously is much harder than elsewhere, but this offers no serious impediment to the operation, therefore it seems unwise to sacrifice a tooth

The opening may be made with a common trochar but a bone drill answers the purpose better The drill may be worked by a dental engine, but this is unnecessary, as with a conical burr bone drill the opening is easily made by hand in three or four minutes Care should be taken to hold the drill so that as it enters the cavity it may not plunge suddenly through and wound the opposite wall The opening should be drilled on a line with the internal canthus of the eye upon the same side, which insures striking the central position of the antrum providing it is of normal shape Occasionally the antrum varies much from the typical size and shape, and in a few instances bony septa have been found traversing it In cases of this kind it is necessary to scrape out the partitions sufficiently to allow thorough cleansing

It is best to make a comparatively large opening about a quarter of an inch in diameter in order that it may be easily kept free, and that drainage and washing may be perfect During the treatment the opening should be filled with a roll of cotton or gauze to prevent the entrance of food and to delay healing until

the lining of the cavity has become healthy, or it may be kept patent by a small metallic tube which a dentist may fasten to an ordinary plate and which may be closed while the patient is eating by a small cork After the operation the subsequent treatment of the case consists of washing out the cavity with antiseptic and astringent solutions I have used with greatest satisfaction a spray or small injection of per oxide of hydrogen three or four times a week and a wash of listerine ʒss—ʒi to ℥i of saturated solution of boric acid twice a day This wash should always be used luke-warm

If there is no necrosis of bone the case may be expected to recover in from two to six weeks, though occasionally a tendency to renewed inflammation may make it expedient to keep the opening much longer

I have seen six cases of this disease

Case 1 was that of a man about twenty five years of age who came to me six or seven years ago He suffered no pain and complained only of catarrh There was a free opening into the naris and the dis charge was not very abundant The annoyance was so slight that he disliked to have the antrum opened I saw him about five years later and found him still in the same condition He had done nothing for it and still objected to the necessary operation

Case 2 Mrs A D C, æt 44, came to me from Wisconsin two years ago For one year had been troubled with discomfort and often pain in the left cheek, which became worse and swelled whenever she took cold She was also annoyed by a purulent discharge from the nostril and into the throat I found that there had been a spontaneous opening into the mouth which had left a small fistula, but it was so small that pus constantly filled the antrum and escaped from the nose I had the cavity syringed out through this small opening twice a day with a satur ated solution of boric acid In three weeks the purulent discharge had entirely ceased, but the washing was continued less frequently for four or five weeks longer The patient had suffered slightly for eight years with rheumatism, which may possibly have been the cause of the disease in the antrum For this she was given small doses of iodide of potassium She returned to her home apparently perfectly cured and I have reason to believe there has been no return of the disease

Case 3 Mrs J L F, æt 48, came to me in February of this year complaining of pain in the left cheek with some purulent discharge into the left naris The trouble had begun four years previously when she had had her teeth drawn I found that there had been a fistulous opening near the site of the canine tooth, but of this there now remained only a *cul de sac* about three eighths of an inch in depth and an eighth of an inch in diameter Through this I perforated the antrum with a drill, and subsequent ly washed the cavity with peroxide of hydrogen and had her inject it twice a day with a warm saturated solution of boric acid At the end of three weeks all purulent discharge had ceased and the patient felt perfectly well She then returned to her home with instructions to continue the wash for two or three weeks

Case 4 E R, at 34, came to me March 8th, 1887 He had suffered greatly with the nasal symp toms of suppurative inflammation of the antrum for about two years, though during a part of that time he had been free from the symptoms This had been caused by a diseased tooth which the dentist had tried to save until six months previous to his consulting me—when it had been drawn Subsequently he seems to have nearly recovered, but for two months he had been greatly distressed by the offensive discharge into his throat I opened the cavity with a large drill at the site from which the first molar had been removed and subsequently washed the cavity as already recommended At the end of three weeks there was very little purulent discharge but the opening was closing rapidly I did not see the patient for a week afterward, but he then reported that two or three days after his last visit the opening closed completely and remained so a few days when he again began to have pain in the cheek I then enlarged the canal with the same drill and renewed the treatment Three weeks later the secretion of pus had entirely ceased There was no secretion of pus for a week afterward, when he caught a bad cold and the cavity filled with muco pus in thirty six hours, during which time he had omitted to remove the pledget of cotton from the opening In this case the inferior turbinated body was greatly swollen and the opening into the nostril from the antrum comparatively large I thought that the secretion from the nose had filled the cavity, I therefore cauterized the turbinated body to reduce its size Continued the same local treatment and directed him to have a tube fitted to the opening to keep it patent for several months He did not follow this advice, but allowed the opening to close, however, there has been no purulent discharge since

Case 5 Mrs I, æt 36, sent to me from Minnesota March 22, 1887 Suppurative inflammation of right antrum, due to a diseased tooth, of a year's duration I opened the antrum as in the last case and used the same local treatment At the end of three weeks all purulent discharge had ceased and it has not returned But the cavity was kept open for two months and then she was directed to leave out the cotton and allow it to heal Recovery seems perfect

Case 6 A young woman æt about 25 Has complained of catarrh for many months, and recently of swelling of the right cheek and a gum boil near right canine tooth The symptoms and signs in this case are very indistinct, but Dr Brophy confirms my sus picions of suppurative inflammation of the antrum I expect to open the cavity soon

64 State Street, Chicago, June 9, 1887

SOME CASES OF COMPOUND FRACTURE, WITH REMARKS ON TREATMENT

BY J A WESSINGER, M D,

OF HOWELL MICH

MEMBER MICHIGAN STATE MEDICAL SOCIETY CORRESPONDING MEMBER DETROIT MEDICAL AND LIBRARY ASSOCIATION

Case 1 —About noon on June 19, 1886, H M,

æt 32, married, railroad conductor by occupation, was thrown from his train immediately in front of a flat car which was backing up at a rather high rate of speed, both wheels of the rear truck passing over patient's legs below the knee I saw the injured man about forty minutes after the accident He was suffering somewhat from shock, from which, however, he soon rallied under mild stimulation He was placed in a large room on the first floor at his boarding house A bed having a hard mattress was used, and all furniture removed from the room except a table and chairs Preceding the anæsthetic I gave a hypodermic injection of ⅙ gr morphia Anæsthesia was then begun with pure chloroform (Squibb's) In fifteen minutes the patient was thoroughly under the influence of the anæsthetic An examination of the injured parts was now begun After removal of the clothing we found a compound comminuted fracture of both bones of the right leg, and extreme laceration of all the important soft tissues, both the anterior and posterior tibial arteries were severed, but hæmorrhage had not been severe The tibia and fibula of the left leg were fractured through the upper third On consultation with other surgeons present it was decided to amputate the right leg below the knee, the left leg to be treated with suitable splints After adjusting the Esmarch bandage, I performed bloodless amputation by the antero posterior flap method, four inches below the right knee The instruments, sponges, and ligatures used during the operation, were kept in a 10 per cent solution of carbolic acid

After the amputation was completed the stump was irrigated with bichloride solution, 1 1,000, then the flaps brought together with silver wire, a drainage-tube inserted, and the stump dressed with dry antiseptic gauze held in place by a few turns of the roller bandage The fracture of the left leg was then reduced and suitable wooden splints adjusted By this time the patient had recovered from the anæsthetic, another hypodermic of ⅙ gr morphia was given, and our patient left to rest in a clean bed which had been prepared during the operation Everything looked favorable for a good recovery During the evening of the same day I saw patient again, he had taken some light food, bowels and kidneys had operated normally He seemed to feel cheerful, and congratulated himself on his escape from more serious results during a railroad accident

June 20 At 9 A M I saw patient again Temp 99°, pulse 90, full, soft, regular, some pain at seat of fracture, no pain in stump Patient had slept well after midnight on having taken ⅛ gr morphia Had taken breakfast of beef-tea, eggs and milk Patient cheerful and comfortable At noon of this day I received notice, purporting to have come from the patient, that my services were no longer needed and that other physicians had taken charge of the case Nothing was said, and the man left to his fate I afterward learned, to my chagrin, that the methods by which the patient passed into other hands were much more unique than honorable Suffice it to say that all antiseptic methods of treatment in this case were now discarded, the stump was left open, and simply a cold water dressing applied, which was renewed daily The fracture was put up in plaster of-Paris, *no cotton batting was used*, simply a drawer leg between the plaster and the man's skin (a most lamentable and inexcusable blunder) I soon heard that the patient was going from bad to worse, the limb that had been "done up" in a plaster of Paris vice (for such it was in this case) became intensely swollen, the foot discolored, and finally, at the earnest solicitation of the patient, the plaster was removed, when a large slough presented itself on the inner aspect of the limb over the seat of fracture This sloughing surface separated, and the injury was thus transformed from a complete to a compound fracture with very unhealthy condition of tissue surrounding The cold water treatment was continued as before Condition began to be more unfavorable from day to day, until the twelfth day after injury, when a wild delirium developed, with a high temperature (104 5°, according to the nurse), some emesis, anorexia, diarrhœa, profuse sweating, granulation process in stump has ceased, sloughing process in left leg extending, and emitting a very offensive odor

At this time Dr W J Herdman, of Ann Arbor, Mich, surgeon in chief of the road, saw the patient, and gave a very unfavorable prognosis, as the man was suffering from advanced septicæmia At the earnest solicitation of the relatives of the patient, I saw him again on the twenty seventh day after the accident The only thing to do at this stage of the case was to pay the last tribute of relief to a dying man, and I so informed the friends I found the patient almost pulseless, markedly tympanitic, a low muttering delirium Temperature 97°, involuntary green stools, urine offensive I also found a large abscess in the left thigh which, on being incised, discharged a large quantity of fetid pus Another large abscess was detected between the muscles above the crest of the ilium on the right side, this was filled with a mass of stinking pus The stump had not healed and was sloughing, the fractured bones in the left leg were bare, and the upper fragment of the tibia was denuded of periosteum about 1½ inch back from line of fracture The bones had not united and were being rapidly disintegrated at the injured points I irrigated the wounds thoroughly with bichloride solution (1 1,000), and put the patient on brandy, quinine, and digitalis However, he did not rally, and finally died on the thirtieth day from date of injury He was markedly jaundiced, and probably the subject of pyæmic (metastatic) abscess of the liver No autopsy

Case 2—C R A, male, married, æt 24, has always been healthy By occupation a brakeman on railroad About noon on June 29, 1886, while unloading gravel from a construction train, the wire cable struck the patient on the right leg with sufficient force to produce a compound comminuted fracture of the tibia in the lower third I saw the patient about ten minutes after accident His condition at this time was as follows No shock, very little hæmorrhage, large lacerated wound in lower third of right leg, fragments of bone exposed to view The patient having been anæsthetized, and the wound

thoroughly irrigated with a 1 1,000 bichloride solution, I proceeded to repair the injured parts Found the upper end of the tibia broken squarely across, while the lower part was fractured obliquely, very ragged, and denuded of periosteum to about one inch below the line of fracture All fragments of bone and lacerated tissue were carefully removed, the bone denuded of its periosteum was exsected, and a free opening made through the limb posteriorly for drainage All operative measures having been completed, the wound was again irrigated with the bichloride solution, a drainage tube inserted, and the wound dressed with moist sublimated cotton The limb was now placed in an ordinary fracture box having a slot over seat of injury, and moderate extension applied The combined length of bony fragments removed was 1¼ inch The wound began to repair immediately, the patient had no untoward symptom, the temperature reached 101° on but two occasions, and at eight weeks from date of injury the patient was able to walk on his foot The moist sublimated dressing in this case was renewed every twelve or twenty four hours, and continued until the wound had been filled in with granulations, when the moist dressing was withdrawn and dry boric acid dressings substituted This was continued until the healing process in the wound was complete This man began work again as watchman at a railroad crossing ten weeks from date of injury, here he received a slight injury at the point of fracture, which, however, was soon repaired by rest to the limb, by means of a plaster splint adjusted by Dr W J Herdman, of Ann Arbor, where the patient was living at this time I saw the patient about two weeks ago, when he was in all respects as sound as ever, although a shortening of about ¼ inch was still present

Case 3 —Wm P , æt 55, married, carpenter Has never received a severe injury, but is addicted to the use of alcoholic drinks On August 21, 1886, he fell a distance of twenty five feet, striking first upon the heel of his left foot, then upon the left knee I saw the patient about ten minutes after the injury On examination under an anæsthetic, I found dislocation outward of the astragalus, with Pott's fracture of the fibula, and a compound complicated fracture of the tibia and fibula in the upper third of the same leg, the injury at this point consisting of a transverse fracture of the tibia and fibula three inches below the knee joint, and also a longitudinal fracture of the tibia running into the joint The outer and inner tuberosities of the tibia were both distinctly movable Over the line of transverse fracture was a deep penetrating wound caused by a large nail or other pointed object Hæmorrhage was quite severe, patient suffered somewhat from shock, from which, however, he soon recovered I reduced the dislocation at the ankle joint and placed the lower limb in Koehler's adaptable splint (carbolated) Adjusted the fractures above, and irrigated the wound with 1 1,000 bichloride solution The whole limb was then placed in a fracture box, with moderate extension and counter extension, and the wound dressed daily with moist sublimated cotton

On the third day after date of injury the temperature was 103° Pulse 110, hard and bounding I began to feel fearful of my patient Suppression of urine and fæces I used a Nélaton's catheter, which relieved the bladder, and gave a brisk cathartic On the fourth day the temperature had gone down to 100°, pulse 110, patient feeling better, circulation in foot good From this date temperature and pulse gradually went down until the end of the second week, when both were normal, where they remained until recovery Patient began to eat, bowels regular, sleeps well This course was not materially changed until November 10, 1886, or ten weeks from date of injury, when patient began to walk with crutches, and at the present writing the patient's limb is practically as good as ever, although there is about one half inch shortening, with some contraction of the plantar fascia

Case 4 [1]—Male, æt 26, married On September 8, 1884, while riding over a bridge on a traction threshing engine, the bridge suddenly gave way, precipitating engine and patient into the river below In this accident the right limb of the patient was caught between the heavy traction chain and the forward wheel of the engine, thus producing an extensive lacerated wound, with an oblique fracture of the tibia at the middle of the lower third of the leg I saw the patient shortly after the accident, and found him suffering somewhat from shock, and faint from the loss of blood Several fragments of bone were removed, and the bleeding vessels controlled by torsion and ligature Splints were adjusted with an aperture over seat of injury, and the wound dressed with carbolized cotton This was laid aside on the third day after injury, owing to symptoms of carbolic acid poisoning, and iodoform dressings used instead, which were renewed daily The temperature in this case did not go above 102°, and no untoward symptoms developed from day of injury until final recovery, with the exception of the slight toxic effects of the carbolic acid The patient has a sound limb, and is able to follow his vocation as a farmer

Case 5 —Male, æt 14 On October 16, 1886, he sustained a compound dislocation of the ring finger at the metacarpo phalangeal articulation The injury was caused by a base ball striking the end of the finger with great momentum, throwing the phalanx out so that it rested on the dorsum of the hand I saw the patient about ten minutes after the accident Very little hæmorrhage Advised amputation, but this was refused by the parents I then reduced the dislocation, irrigated the wound with bichloride solution, applied a splint to the palmar surface of the finger, and dressed the wound with moist sublimated cotton This dressing was renewed daily, with bichloride irrigation The wound began to heal immediately, and on November 23 the patient was discharged cured, with a useful though somewhat deformed finger

Remarks —In *Case 1* we have a man than whom none had better prospects of recovery at the beginning, yet as soon as antiseptic treatment was withheld the patient began to fail His wounds ceased

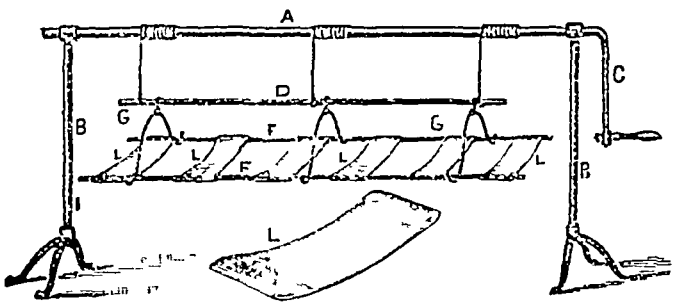
[1] Reported in Medical Age vol iii p 292

to heal, became very fetid, and he went down under the devouring fire of septic poison In the other four cases antiseptics were rigidly adhered to, the wounds were free from odor, healthy in appearance, and the process of repair went steadily on to recovery In *Case 1*, could the exact condition of the injured bones in the left leg have been known, a synchronous amputation might have saved the patient's life In treating these severe injuries the following are some of the precautions necessary

1 Close attention to all the details Keep all general attendants away from the wounds 2 Absolute rest at the point of injury 3 Look closely after the general health of the patient Don't take anything for granted 4 See that a proper mental and physical balance is maintained

Absolute rest at the point of injury cannot be too strongly emphasized, since success or failure in treatment depends largely on the attention that is given to this principle

In this connection I desire to call attention to a device which has been of inestimable value to me in the treatment of these cases This apparatus is original with Dr W J Herdman, of Ann Arbor, Mich, and is known as "Herdman's Lifting Device" This apparatus is simple in construction, durable and cheap It is made of ordinary gas-pipe and wrought iron, and any ordinary machinist can make one One man can lift a patient from the bed without causing any pain whatever, and at the same time greatly add to the comfort of an injured person, while a change of bedding or other clothing is being made The following cut will fully illustrate the construction of the device One thing to be remembered in constructing this device is, that the cross-bands must be the same in length as the distance between the cradle hooks



HERDMAN'S LIFTING DEVICE

A, cross bar B, legs C, crank D, cradle L, L, L, L cross bands, loop stitched at ends for sliding bar F, sliding bar G, cradle hooks The device should be long enough to swing over the bed The cradle is then lowered, the bands passed under the patient, the sliding bars passed through the looped ends of bands, then into the hooks, when a few turns at the crank lifts the patient bodily from the bed

Finally, in the language of a well-known writer [2] "In the light of the researches of experimenters in the field of bacteriological science, and the experience of those who, acting upon the suggestive results derived from these experiments, treat wounds antiseptically, in my opinion, the surgeon who does not take into account every possible source of danger that may overtake his patient, including in this the noxious influences arising from the entrance of germs into the tissues, is criminally negligent, and directly responsible, both to his own conscience and to the world at large"

I am greatly indebted to Dr H N Spencer for valuable services rendered during the treatment of these cases

[2] Geo R Fowler, M D, in New York Medical Journal

ON THE TREATMENT OF FELON WITHOUT INCISION

Read in the Section on Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY L DUNCAN BULKLEY, A M, M D,

ATTENDING PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, ETC

The teachings of instructors in surgery, and also those in the text books on the subject, are all to the effect that felon, paronychia, or whitlow, will require sooner or later a free, deep incision, even to the bone, and that in the majority of cases the sooner this is done after the diagnosis is made, the better I believe, also, that careful inquiry would show that this is the almost universal practice both of those who follow surgery more particularly, and of general practitioners But little is found in writings in regard to the medical and internal treatment of these cases, other than the suggestion that tonics are often needed, and the almost universal recommendation is that poultices should be applied, both before and after the incision

Having had quite a considerable number of cases of felon under my care in public and private practice, some of them being very severe, and having pursued a very different course of treatment from that usually followed, as far as I can learn, I beg to present the matter briefly, in order that others may make trial of the same methods, which, as I believe, have advantages worthy of consideration

I will not attempt to enter into any anatomical or pathological study of the parts concerned, or of the affection under consideration, but in order not to be misunderstood I wish to state that by felon and whitlow I refer to the cases familiar to all, in which there is deep seated inflammation, mainly of the ends of the fingers, tending to penetrate even to the bone, and ultimately, if unchecked, to cause necrosis of the same Some of my cases have been light and have remained superficial, others have been first seen when the inflammation had already penetrated deeply, when the finger was hot, tense and hard, and exceedingly painful on pressure, and even after the patient had already passed sleepless nights with the throbbing pain But for many years I have never incised a case, other than a possible slight prick, without pain, into dead skin after the pus had become superficial, nor have I ordered a poultice for such a case within the same period of time

While a certain number of cases of whitlow seem to have their origin deep in the tissues of the finger, or even in the periosteum, in the majority of cases the inflammation appears to originate, and probably does, in a relatively superficial injury, as a prick of a pin, or needle, or nail, a scratch, or other appar-

ently trivial accident, to which little or no attention is paid at the time As is well known, when the inflammation has once started it proceeds with considerable rapidity, and three or four days after its beginning the patient may be suffering agony from the deep seated, tense, throbbing pain, and the entire tissues of the finger are found to form a firm, hard mass, exquisitely sensitive to pressure

The reason for the ready and rapid extension of the inflammation from the superficial to the deep structures is undoubtedly found in the anatomical peculiarities of this part, which consist in the existence of fibrous threads extending from the skin to the periosteum, binding all the parts firmly together, along these connective tissue bands the inflammation travels from without inward with ease, and it is also because of the existence of these connecting fibres that, under the treatment now proposed, in a deep-seated inflammation, originating even in the sheath of a tendon or the periosteum, the pus may find exit without causing great damage, as will be presently shown

As an element in the production of whitlow the general condition of the patient must always be taken into consideration, and especially that unknown but still recognized state manifested by the tendency to form pus, the pyogenic habit, as it was formerly called Every prick of a needle or nail in the end of the finger does not result in a felon, nor in a given number of subjects could it be produced in any great proportion of instances by any amount of injury to the finger tip, nor can it be produced at will even in those who are ever so much run down in health, as in so many other conditions of disease, some predisposing cause which causes what might otherwise be an innocuous prick to become the beginning of a serious inflammatory process Its localized phenomena would almost point to an infectious origin, received with the wound, were it not that many cases originate deeply without external puncture

The treatment which I would advocate, and which has proved valuable in my hands, consists both of general and local measures, and has for its aim the checking of the inflammatory and suppurative process rather than the encouragement of suppuration, as is ordinarily done by poultices

Patients even with a beginning felon are commonly found to be in a state of lowered vitality, often with more or less of a sluggish condition of the digestive organs, coated tongue, loss of appetite, etc Unless it is contraindicated I generally begin the treatment with a mild cathartic, the following being that commonly employed

℞ Ext colocynth comp
Mass hydrarg ää gr x
Pulv ipecacuan gr ii
M Div in pil No iv Sig Take two at night and two on the second night after

A tonic is administered from the first, one containing iron being preferred, that usually given is a combination known as Startin's mixture, which has considerable power in controlling inflammatory affections of the skin The formula of this is as follows, the proportions being somewhat altered to suit individual cases

℞ Magnesii sulphatis ℥i
Ferri sulphatis ℥i
Acidi sulphurici dil ℥iv
Syr zinziberis ℥i
Aquæ, add ℥iv
M Sig Teaspoonful in water, through a tube, after eating

In addition to this it is my custom to administer the sulphide of calcium (calx sulphurata) from the beginning to the end of the treatment I usually give it in the form of ¼ grain gelatin coated pills, one being given every two hours irrespective of food or other medicine In order to have any good effect from this latter drug it is essential that it should be fresh and pure, for, as is well known when exposed to the air it rapidly loses its free sulphur and becomes converted into the inert sulphate of zinc, or gypsum It cannot, therefore, be well given in powders or tablets, nor even in extemporaneous pills, but is best administered in those well coated with gelatin, which preserves the drug unaltered, it is well, however, to test the pills by biting them, when the characteristic odor of sulphuretted hydrogen becomes at once noticeable if the article is good

Some attention to the diet should also be paid in these cases, and specific directions should be given Alcohol in all forms should be absolutely interdicted, and the malted liquors appear to be also very harmful The diet should be full and nourishing, but not stimulating Milk is often given, sometimes in the form of punch and egg nog, but, as I have elsewhere explained very fully, I believe that milk is not a desirable article to take in connection with other food, and my constant direction is that it should be avoided at the meals On the other hand, it serves a most admirable purpose in raising the vital tone of these patients if given separately and alone, in the interval between the meals, preferably one hour before each meal, and late at bed time, avoiding, however, taking it within half an hour of the granules, or of any other substance in the stomach Tea and coffee may be taken in moderation, but unnecessary and indigestible articles should be avoided

The local treatment of felon which I have followed has the merit of great simplicity and is one which can be readily followed out by every one It consists simply in the constant any very thorough envelopment of the affected part in a protective ointment from the beginning to the end of treatment The application used is the diachylon ointment of Hebra, which, when properly prepared, forms a most agreeable and soothing dressing

Of late years it has been suggested to make the diachylon ointment by melting lead plaster with various oils, or vaseline, and much that is supplied on prescription will be found to be prepared in this manner But this by no means answers as well in many conditions of the skin as that prepared according to the original formula given by Hebra, probably because the added portion of the oil has not undergone decomposition with the litharge I am therefore very particular to have the ointment prepared according to the original formula, which is as follows

℞ Olei olivarum optimi -- ℥xv
Plumbi oxidi ℥iij ℥vj
Olei lavandulæ ℥ij

℞ Add the oil to two pounds of water and heat it with constant stirring, the litharge is to be slowly sifted in while it is well stirred, fresh water being added as required The ointment is to be stirred until cold, and the oil of lavender then added *In winter a slightly larger quantity of oil is required to make a soft ointment*

When properly made according to the above directions the ointment is soft and unctious, and not very sticky It is to be spread upon the woolly side of lint *very thickly*, even a quarter of an inch or more in thickness, so as to completely envelop the end of the finger in a thick mass of the ointment, this is then lightly bound on and left undisturbed as long as possible, generally it is best to renew the application twice daily, and if there is no discharge the same dressing may have fresh ointment spread upon it, and be replaced quickly The affected part should not be handled at all, nor the ointment scraped off even, the idea being simply to keep it continuously in the mass of bland, protective and absorptive ointment, to allow the inflammatory process to subside

The first application of the ointment is described as being soothing and pleasant in the extreme, in mild cases just beginning it allays the irritation and pain at once, and even in those who had had sleepless nights from the pain, I have had them tell me that the relief was almost complete, and that they had slept the night after the application although in one or two instances the relief was more gradual

Under the treatment above described some suppuration commonly takes place In lighter cases, where the inflammation has begun superficially, one or more small points appear beneath the epidermis, which either break themselves or may be opened absolutely without pain through a slight prick in the dead covering In those where the disease has begun more deeply, or where it has penetrated to some depth before treatment, the progress is more slow, and a week may be taken before the pus comes near the surface, but then it shows itself also in one or more points, never very large, and the discharge may be hastened by a slight prick through the dead epidermis

In one or more cases under my care small spiculæ of bone have been discharged, but still the case progressed satisfactorily without deep incision After the opening the ointment is to be still continued in the same manner, the dressings being renewed more often if there is much discharge, until finally the openings close and the parts resume a normal condition

The duration of the treatment of these cases compares very favorably with that of those treated in the ordinary manner with poultices and incision I do not think that any of them have been obliged to use the ointment more than three weeks, and in the milder cases all trouble has sometimes subsided in a week or ten days

My first cases were treated in this manner fully ten years ago, since which time I think I have applied the treatment to a dozen or more cases in public or private practice I cannot, of course, vouch for all the cases I have seen, as to the final results, as all know the uncertainty attending out patients in hospital practice, but I know of the complete success in a number of this class, and could give histories from notes of cases seen in private practice if time permitted

A single case may be briefly mentioned Mr J B , a gentleman aged 38, is now under treatment for another trouble, two years after his felon, for which I treated him in this manner In this case there had been intense, deep pain, which was relieved almost entirely by the ointment About a week after beginning treatment pus was discharged and several spiculæ of bone followed, but all healed quite rapidly, and now, when examined recently, the scar on the right forefinger is seen to be supple, and the integrity of the finger perfectly preserved

I am quite aware that there may be cases in which this plan of treatment may not be applicable, but such have not as yet come under my observation I shall look with interest for the experience of those who have opportunities of seeing more cases, and more severe ones, perhaps, than have come under my care, and feel confident that if the plan of treatment I have sketched is carried out thoroughly, it will be found to give good results certainly in a share of cases, and will certainly prove more acceptable to the patient than the annoying application of poultices and the much dreaded incision with the knife

DISCUSSION

DR NORMAN BRIDGE, of Chicago, had used vaseline, cosmoline and belladonna applications

DR NORTH, of Waterbury, had immersed the finger in a strong solution of iodine, where pus was not already formed, with good results He immersed the finger three times a day for five minutes each time

DR POWELL, of Indiana, had used oleate of morphia to relieve pain, keeping some constantly applied It has given great relief

DR ZEISLER, of Chicago, said that ichthyol relieves pain to a great extent, even if it does not prevent suppuration

DR LOSS, of Pennsylvania, has dipped the finger in hot water for a half hour and then dipped it in collodion

DR C C P SILVA, of Chicago, said that water at a high temperature will prevent suppuration if abscess is in its incipiency and superficial Water will not do so if the process is deep seated

DR PORTER, of New Hampshire, had used water and iodine For last five years he has used iodine and then pressure, by a plaster and roller bandage, using as much pressure as the patient will bear without severe pain Pressure on the muscles may prevent congestion and suppuration

MEDICAL PROGRESS.

TROPHIC NERVES —The actual demonstration of the existence of trophic nerve fibres, apart from vaso motor fibres, has not until recently been made, although many evidences pointing to that conclusion have been put forward DR JOSEPH, of Berlin, in a number of experiments on cats, produces facts which go to prove the existence of trophic nerve fibres in the peripheral nerves The complication of vascular changes induced by the removal of the vaso motor fibres from a part must be excluded in order to prove definitely that any nutritive changes occurring after section of its nerve are due to the loss of trophic influence These conditions were carefully considered, and in order to avoid any vaso motor changes, the second cervical nerve was selected for section, which, as will be seen, contains no vaso-motor fibres This nerve was used in all the experiments Mere section of the trunk of the nerve produced no effect, as reunion rapidly took place, so that it became necessary to remove a considerable portion of the trunk to prevent this occurrence In some of the animals the ganglion on the posterior nerve root was also removed The changes induced were limited to the area of distribution of the nerve, and in those where the ganglion was removed similar changes occurred in the cutaneous area of distribution of the fifth cranial nerve of the corresponding side, coming on in different animals at a period varying from five to twenty seven days The changes consisted in loss of hair, at first localized, afterwards gradually extending, situated above and behind the ear where the trunk was only severed, above the eye and over the cheek, where part of the trunk and the ganglion on the posterior root were removed After a time complete baldness and a shiny atrophied state of the skin made their appearance No increased vascularity, inflammation, or any other change whatsoever could be discovered in the skin The hair was examined for parasites, but none could be found Microscopic examination of the skin failed to detect anything beyond atrophy of the hair follicles, there was no evidence of inflammatory or other changes From these experiments Dr Joseph concludes that trophic nerve fibres exist apart from vaso motor fibres, and entirely independent of them, and he explains the similar changes in the area of distribution of the fifth cranial nerve by assuming that it derives its trophic supply from the ganglion on the posterior root of the second cervical nerve from which fibres join the ascending root of the fifth —*Virchow's Archiv*, Bd cvii, Hft 1 —*The Practitioner*, July, 1887

THE ACTION OF ACONITE UPON BODILY TEMPERATURE —DRS LAUDER BRUNTON and J THEODORE CASH have, in a research upon the action of aconite upon bodily temperature ("St Bartholomew Hospital Reports," vol xxii), reached the following conclusions

1 That in pigeons aconite acts as an antipyretic, both in large and small doses

2 This antipyretic action is exerted whether their body temperature be normal, or be artificially raised, or artificially reduced, at the time of the injection of the drug In all cases the injection causes the temperature to fall

3 This fall is usually less in birds which have been artificially cooled than in birds whose temperature is normal, or has been raised artificially

4 The action of the drug is apt to be modified by individual peculiarities in the birds which we are at present unable to explain

5 The temperature returns more rapidly and completely towards the normal when the birds which have got aconite are kept in a warm place, although the primary fall induced by the administration of the drug may have been as great as, or greater than, that observed at medium temperatures

6 A repetition of the dose after the effect of the first one has passed off causes a fall which is apparently uninfluenced by the first dose

7 It is occasionally noticed that a large dose may cause a fall of temperature which is smaller but more prolonged than that caused by a smaller dose

8 In guinea pigs cooling appears to retard the fall of temperature caused by the drug, and also to retard the return to the normal

9 The temperature of animals exposed to a heated atmosphere is but little affected by aconite, in fact, large doses may diminish the resistance of the animal to the effect of external heat, and cause the temperature of an animal to rise higher than that of one to which no aconite has been given

10 If the animal be exposed to cold when the drug is administered, the fall of temperature is both more rapid and more extensive than in the normal animal —*The Therapeutic Gazette*, April, 1887

HÆMOGLOBINOMETRY — In the *Correspondenz Blatt für Schweizer Aerzte*, No 10, 1887, p 299, Dr Herman Sahli, of Berne, writes that, having found Gower's hæmoglobinometer practically useless in artificial light, in consequence of the apparatus having too high figures under such conditions, he has prepared a new standard mixture of picric acid and carmine, which, under artificial illumination, has the same optical properties as a 1 per cent solution of hæmoglobin In daylight the color of the two solutions is quite different When the comparative procedure is undertaken, the tubes (one containing the blood to be examined, another containing Sahli's solution) must be placed against the white globe of a petroleum lamp or against a sheet of thin white paper held between the tubes and a candle A series of control experiments showed that the results obtained by examining the blood with Sahli's solution in the evening, were almost identical with those given by the usual method in daylight —*The British Medical Journal*, July 9, 1887

THE TREATMENT OF LUPUS BY INJECTIONS OF CORROSIVE SUBLIMATE —DR INGINIO TANSINI, of Lodi (*Gazetta degli Ospitali*, June 12th), narrates the treatment of a case of lupus of the nose and face by

means of repeated injections of corrosive sublimate He began with a weak solution corrosive sublimate 50 centigrammes, distilled water 100 grammes This produced no reaction of any kind A stronger solution—corrosive sublimate 1 gramme, distilled water 100 grammes—was then used This produced some tumefaction and œdema in the neighborhood of the punctures, and slight suppuration in some of them Some fourteen or fifteen injections of a few drops were practised Improvement soon became marked, and eventually all traces of the disease disappeared, the only marks left being those of the punctures in which suppuration had taken place Dr Tansini was led to try these injections by the following considerations 1 That lupus is a form of tubercle 2 That the bacilli are few and have no tendency to diffuse themselves 3 That corrosive sublimate has proved certainly destructive to bacilli He claims advantages for this method on account of lessened pain and disturbance and superior cosmetic results —*The Lancet*, July 9, 1887

THE FUNCTION OF THE URETERS —A SAMSCHIN, after referring to observations made by others in cases of exstrophy of the bladder and vesico vaginal fistula, reports his own experiments in a case exhibiting a large *recto-vesico-vaginal* fistula, in which, with the aid of a speculum, he was able to expose the openings of the ureters plainly to view His conclusions are as follows

1 Contraction of the ureters takes place in both man and the lower animals in a peristaltic manner Each contraction results in the discharge of a variable quantity of urine

2 The contractions at the vesicle orifices of the ureters do not take place synchronously

3 The number of contractions observed at the orifice of a ureter in a given time is not constant, but is found to vary with each observation

4 The total quantity of urine discharged by each ureter in a given time varies, as well as the average quantity discharged by each in a single contraction, the latter quantity varies between 8 and 2 ccm

5 The maximum of quantity discharged by a single contraction amounted to 4 ccm

6 No increase in the number of contractions was observed to take place after the copious injection of fluids —*Centralbl f Gynak*, No 19, 1887

SEDATIVE ACTION OF ANTIPYRIN ON THE SPINAL CORD —M CHOUPPE, at a recent meeting of the Société de Biologie, described experiments which confirm those of Germain Sée in regard to the diminution of reflex excitability by antipyrin M Chouppe's experiments consisted in attempts to neutralize the convulsive action of strychnine by antipyrin In this he was successful With a dog to whom strychnia had been given in doses that produced convulsions so severe as to make death imminent, it sufficed to use 2 grains of antipyrin hypodermically to render breathing once more regular and natural

In the discussion which followed M Gley called attention to the well known fact that large doses of antipyrin produced convulsions similar to those of strychnine poisioning, and asked how this fact was compatible with a lessening of reflex excitability in the cord M Brown Séquard suggested that the opposing action of antipyrin to strychnine might be similar to the opposing action of different bromides and some other substances For instance, bromide of potassium alone will produce bromism which the same dose of mixed bromides will not

M Laborde claimed that as a general rule it was true that substances that in small doses were anticonvulsive, in large doses were convulsives, and vice versa —*Semaine Medical*, July 6, 1887

SIMPLE METHOD OF ARTIFICIAL RESPIRATION —In the *Brit Med Jour (London Med Record)*, MR J A FRANCIS describes a simple method of artificial respiration which, he alleges, combines all the advantages of the Marshall Hall, Sylvester and Howard methods, without any of their disadvantages The plan is as follows

The body of the patient is laid on the back, with clothes loosened, and the mouth and nose wiped Two bystanders pass their right hands under the body at the level of the waist, and grasp each other's hands, then raise the body until the tips of the fingers and the toes of the subject alone touch the ground, count fifteen rapidly, then lower the body flat to the ground, and press the elbows to the sides hard, count fifteen again, then raise the body again for the same length of time, and so on, alternately raising and lowering The head, arms and legs are to be allowed to dangle down quite freely when the body is raised The author alleges that this method is most successful, and is so simple that any one can perform it without any teaching

ADMINISTRATION OF PHOSPHORUS —SOLTMANN recommends an oily solution, 1 500 Gr iij of phosphorus are dissolved in ℥iij ⅛ of oil of almonds over a water bath If the phosphorus has been previously dried thoroughly, and the process carefully conducted, no phosphorus is deposited We may order

℞ Phosphorus gr ⅙
Cod liver oil ℥iij ⅛ ♏
S —One teaspoonful daily

Or the following formula may be used

℞ Phosphorus gr ⅙
Oil bitter almonds ℥ij ss
Distilled water ℥ss
Gum arabic ℥ij ss
♏ Make an emulsion
S —One teaspoonful daily
—*Therapeutische Monatshefte*, May, 1887

APOMORPHINE AND MORPHINE IN WHOOPING-COUGH —DR P F FEDOROFF, of Arkhangelsk, states (*Proceedings of the Arkhangelsk Medical Society*, part 2, 1887, p 92) that he has obtained good results in whooping-cough by the internal use of the following mixture —℞ Morphin muriatic gr ij; apomorphin muriatic gr j, acid muriatic ℥ss, aq destill ℥viij, M D S, a tablespoonful four times a day The paroxysms are lessened both in number and frequency after the first few doses of the mixture —*The British Medical Journal*, July 9, 1887

LARYNGEAL SYMPTOMS FROM PRESSURE

In a lecture on "Some Points in Relation to the Diagnostic Significance and Therapeutic Indications of Laryngeal Symptoms resulting from Pressure of Aneurisms upon the Vagus and Recurrent Laryngeal Nerves," DR DAVID NEWMAN endeavors to show by reference to cases of aortic and innominate aneurism 1 That aneurism of aorta and innominate artery may exist and give rise to laryngeal symptoms only, but in most cases, on careful physical examination, certain collateral signs may be made out sufficient to warrant one in forming a positive diagnosis, or to give rise to a very strong suspicion of intra thoracic tumor 2 That in the early stage pressure may cause symptoms of most urgent dyspnœa, accompanied by laryngeal stridor and paroxysmal cough 3 That at a later stage paralysis occurs, usually, but not always, limited to one side, characterized by phonative waste of breath and imperfect cough, but without dyspnœa, except when reflex spasm is indicated on the opposite side, or when pressure stenosis is caused by the aneurism 4 That in certain cases tracheotomy should be performed, not only to prevent impending death from dyspnœa, but also as a remedial measure

Dr Newman gives the records of three cases which illustrate his points, and from which deductions have been drawn The first was one of aneurism of the innominate artery and descending aorta, with paroxysmal dyspnœa from unilateral spasm of right vocal cord, followed three months after by bilateral spasm of adductors, and at a more remote date by bilateral paralysis of adductors In this case the paroxysms closely resembled an attack of laryngismus stridulus, as seen in children There was slight bulging of the sternal end of the clavicle, and evidences of hypertrophy of the left ventricle, but no pulsation over the small area of dulness, situated immediately to the right of the sternum and between the clavicle and second rib The patient had come for treatment on account of paroxysmal difficulty in breathing and a harsh dry cough, the voice being practically unimpaired except during the paroxysms Examination showed the larynx to be healthy, but if the mirror was held in position for even a short time the right vocal cord would be drawn across the middle line and fixed there, and immediately thereafter the patient would have a paroxysm of dyspnœa On postmortem examination the right recurrent laryngeal nerve was found to be completely obliterated In a second case the only symptoms supporting the diagnosis of aneurism were dysphonia, from pressure on the left recurrent laryngeal nerve, and a difference in strength and rhythm of the radial pulses A short time after this there was a development of paroxysmal tracheal dyspnœa, partial suppression of respiration, murmur on the left side, and detection of dull areas along the course of the ascending and descending aorta Laryngoscopic examination showed that the left vocal cord remained stationary in the cadaveric position during attempted phonation, and the apex of the arytenoid cartilage was drawn so far forward that the posterior third of the left vocal cord was not visible The patient had had syphilis, and improved under iodide of potassium

In the third case the patient had occasionally had considerable difficulty in breathing and a severe cough, without expectoration, during the intervals between the attacks of dyspnœa the voice was unaltered Examination of the larynx showed that the cords were completely approximated during phonation, but that the left cord did not respond so actively as the right At this time nothing abnormal could be discovered about the chest except slight hypertrophy of the left ventricle Six months later, however, the physical signs were fully sufficient for a diagnosis The fourth patient only complained of loss of voice In a short time there was dyspnœa on exertion The left vocal cord was found to remain in the cadaveric position during attempted phonation, but on direct pressure with a probe to the left of the arytenoid cartilage the cord moved freely The other symptoms were only sufficient for a suspicion of aneurism, but were more decided four months later

It is well known that death occurs, in cases of aortic aneurism, as a direct result of laryngeal suffocation What is the cause of these attacks of dyspnœa? Reid pointed out many years ago that "severe

dyspnœa, amounting to suffocation, may arise both from irritation and compression of the inferior laryngeal nerves or the trunks of the pneumogastrics For when both, or even one, recurrent nerve was irritated, the arytenoid cartilages were approximated, so as in some cases to shut completely the superior aperture of the glottis," and he explained how paralysis of this nerve, occasioned by compression or other cause, should produce this effect by arresting all the move ments of the muscles of the glottis It has been shown, by Rosenthal, Rutherford, Waller and Prevost, that if the superior laryngeal nerve be divided, and its central end stimulated, bilateral spasm of the glottis will result, the impression is conveyed by the superior laryngeal to the central nerve nuclei, and is thence reflected through the efferent nerves (recurrents) to the muscles on both sides and it is easily understood why pressure on the superior laryngeal or on the trunk of the vagus may reflexly cause bilateral spasm or bilateral paralysis But when the recurrent nerve alone is stimulated, the results are different "A stimulus acting on the efferent fibres generally causes unilateral adduction or abduction of the vocal cord " Pressure on one recurrent nerve is not likely to lead to serious dyspnœa, but pressure on the vagus, by causing spasm of the adductors on both sides, or paralysis on one side and spasm on the other, frequently leads to serious and sometimes fatal laryngeal obstruction

Is the obstruction to respiration due to interference with the function of the larynx, or to diminution in the lumen of the larger air tubes? How can we determine when the dyspnœa is due to abductor paralysis, and when to adductor spasm? The first question is important in connection with contemplated tracheotomy If the dyspnœa be due to laryngeal obstruction tracheotomy will relieve it, otherwise the operation is useless Laryngoscopic examination, therefore, is of very great importance, as without it a needless tracheotomy may be performed As to the value of tracheotomy in suitable cases, it must be apparent that the paroxysms of dyspnœa act hurtfully on the aneurism by causing strain on the walls of the sac, and they are also an immediate danger to life Tracheotomy will therefore permit of rest, and it will obviate the danger of death from asphyxia or rupture of the sac during a paroxysm It may be that the operation will only give temporary relief—but the patient is entitled to the chance

Space does not permit a more extended notice of this valuable paper It may be found in the *British Medical Journal* of July 2

THE AUTOBIOGRAPHY OF DR GROSS

From the press of George Barrie, Esq , of Philadelphia, has just been issued the Autobiograpy of Dr Samuel D Gross, in two elegant octavo volumes, of more than 400 pages each, edited by his sons, Dr Samuel W Gross and A Haller Gross, Esq "It is my wish," the author says in explanation of the writing of an autobiography, "to write a sketch of my life for the gratification of my children and grandchildren, and for the benefit of such members of my profession as may feel an interest in me from my long connection with it " And certainly there can be but little doubt that much good will grow out of this labor to those who read the life's record of the great master of surgery The ambition that can not be stimulated by it must be small indeed Like most men who have made their mark in the world, and one that time cannot efface, Dr Gross began his professional career as a poor man, and with no one to push him into fortune and fame What he did for himself is, in a general way, already known, and what we knew before only added zest to the reading of this book And besides this, there is a charm in reading of the great men of the profession of fifty years ago, sketches made by the man who knew them well, and yet whose hand many of us have grasped

But there are many practical points, and many wise suggestions in the works to which we wish to call attention One of these is that "the voice of the stomach should not be disregarded in eating and drinking As a general rule, whatever the stomach craves may be accepted as an indication as to what is wholesome Some physicians seem to be incapable of interpreting nature, no matter how loudly or energetically she makes her demands" It will be remembered that some years ago Dr Gross published a paper on the "Cravings of Nature" in the *American Practitioner*, and many would do well to read it Apropos of recent attempts to create interest in the subject of a National Bureau of Health, it is now almost thirteen years since, at a meeting of the American Public Health Association in Philadelphia, Dr Gross warmly advocated the necessity of such a Bureau, to be located in Washington, with a branch at the seat of government of each State and Territory "We have," he said, a "minister of war and a minister of the Navy to keep the country in a condition to meet any foreign bloodhounds that may threaten our liberties and deprive us of our territory Why then should there not be a minister of health to see to our sanitary affairs, to enable us the better to cope with the enemies that visit us in our

dwellings So long as we are without well organized government aid, so long will our people from the lowest to the highest pay the penalty of preventable disease "

Dr Gross took very great interest in the American Medical Association, and one of the last acts of his life was to write a paper for the Washington meeting in 1884 In his account of the meeting in Chicago ten years ago he has some remarks concerning the work of the Association, and the quoting of them may cause us to ask if the same may be said now—and may stimulate us to better things in the future "While the American Medical Association has done much good, it has by no means accomplished what it had promised to do, or what had been expected of it While the Transactions contain some excellent papers which would be creditable to a similar body of men anywhere, it contains many others which are entirely destitute of merit, and are disreputable as literary productions The annual addresses in medicine, surgery, midwifery, and hygiene are worse than useless, and are not what such an Association should listen to, covering, as they do, merely the advances made in these branches during the preceding year—a task which any youth of tolerable respectability in the profession could execute as well as any veteran " Fortunately we can say that since this was written many chairmen have departed from that beaten and profitless road, and have delivered addresses on special subjects, leaving the members to do their own research and reading in regard to the year's advances And if any of us deem the above criticism rather harsh, let us remember that it comes from one who was at all times a friend, who had the interests of the profession at heart, who did for his department of American medicine what no one else has done, and who, almost in the hour of death, said of the Association, "Give them my love "

Dr Gross' Autobiography may be obtained in Chicago of Mr W T Keener, 96 Washington street

UNSATISFACTORY MEDICAL APPOINTMENTS

At the recent annual meeting of the State Medical Society of West Virginia, the following preamble and resolution was adopted with much unanimity

WHEREAS, We are assured that in the recent appointment to the vacancy of the Board in the First District, the letter and spirit of the law were violated, and that the character of the appointment in other respects is not such as the profession have a right to expect, in consideration of the dignity and responsibilities of the office

Resolved, That the action of the Governor in making this appointment merits our unqualified disapproval, and that we most earnestly and respectfully call upon him to assist us, by his official acts, to maintain and uphold the law in its spirit and integrity

The law referred to is the Act creating a State Board of Health, and the action of the Governor of that State so " unqualifiedly disapproved," was the appointment of Geo J Garrison, M D , of Wheeling, to fill a vacancy on said State Board of Health If we are correctly informed, the said Dr Garrison had received a diploma only about one year previous from the Jefferson Medical College, of Philadelphia, and that after having attended but *one* regular annual course of lectures, although he had been in practice for several years The same appointment had been protested against by twenty nine of the physicians of Wheeling Such action on the part of the State Medical Society, and of a large majority of the regular members of the profession in Wheeling, is sufficient evidence that the Governor's appointment was not based on any superior professional education or special fitness on the part of the appointee, such as would enable him to discharge the important and responsible duties devolving upon the State Board of Health, in such a way as to command the confidence and respect of the profession and the people of the State It is the frequent recurrence of such mere political appointments to positions requiring high professional attainments and acknowledged ability, that causes so many in the medical profession to doubt the propriety of all legislation having for its object the control of medical education and practice If we are not mistaken it was this act of the Jefferson Medical College in conferring the degree of Doctor of Medicine on Dr Garrison after attendance upon only one annual college course of lectures, that caused the West Virginia State Board of Health to threaten to exclude that college from the list of colleges recognized in good standing And yet hardly twelve months passes before the same cheaply graduated doctor becomes a member of the same State Board of Health by the act of the Governor of the State, in defiance of the expressed wishes of the medical profession of the State

Such appointments, however, are no more reprehensible than the practice of conferring Degrees on *"Practitioners" after one course of college lectures*, that still seems to prevail in some medical colleges, not alone in the rude West or the *malarious* South, but directly in the Eastern metropolis, so called, of medical education and science

THE RELATION OF CONGENITAL MALFORMATION TO MENTAL WEAKNESS —In connection with a trial for

murder, the prisoner having hare lip and cleft palate, the following questions have been asked

Is congenital malformation usually or often accompanied by mental weakness?

Is the subject more liable to unsoundness of mind than other persons?

Can any special relation be made out between malformations of the head (such as the above) and mental weakness?

What is the proportion of such malformations among the insane and feeble minded?

Dr Praskovia N. Tarnovskaia reported at the first Congress of Russian Alienists at Moscow, that 84 per cent of the habitual prostitutes showed various signs of physical degeneration, such as irregularity in the shape of the skull, asymmetry of the face, anomalies of the hard palate, teeth, ears, etc

Any information, statistics, or reference to literature, which will throw any light on these questions will be gladly received at this office, and full credit will be given

ADVANCE REGISTRATION FOR THE CONGRESS — Under the head of International Medical Congress, in another column, will be found the form of *application* in blank, for members of the regular medical profession, in the United States, to *fill correctly* and send, or present in person, to the Chairman of the Committee on Registration, J M Toner, M D, 615 Louisiana Avenue, Washington, D C, with the membership fee, $10, and each person sending the application for registration in advance, by mail, should enclose a postage stamp to pay for return receipt or ticket of admission in return To save our readers the time and trouble of sending to Washington for the form of application, we will include an extra form in each copy of our next week's issue that can be detached for use

NINTH INTERNATIONAL MEDICAL CONGRESS, R R RATES —Let none of our readers, in any way interested in the International Medical Congress of Sept 5, 1887, omit reading carefully the official announcement concerning R R rates over the signature of the Chairman of the Transportation Committee on page 126 of THE JOURNAL for July 23 They will see that the reduced rates apply not only to *members*, but also to members of *their families* We wish to emphasize the fact, however, that all who wish to avail themselves of the reduced rates *must* apply to J W H Lovejoy, M D, No 900 12th St, Washington, D C, for just as many *Certificates* as they have *persons* intending to go Such applications had better be made without delay

SOCIETY PROCEEDINGS.

AMERICAN CLIMATOLOGICAL ASSOCIATION

(*Concluded from page 687, Vol VIII*)

EVENING SESSION

DR FRANK DONALDSON, of Baltimore, read a paper on

CAUSES OF CARDIAC FAILURE IN HIGH ALTITUDES

The important fact that there is often great dyspnœa and sudden cardiac failure on going to high altitudes has not been sufficiently emphasized Many patients are sent for general or special reasons to high altitudes and are thereby done great injury, especially if they suffer from any form of functional organic heart disease From some experiments with the pneumatic cabinet the author had come to the conclusion that this treatment should not be employed in cases in which there is any valvular disease of the heart or fatty degeneration of its walls Before being subjected to treatment in the cabinet an examination of the heart should always be made It has been asserted that the cause of the cardiac failure in ascending to high altitudes is want of oxygen The speaker had performed certain experiments with reference to this point At altitudes within 10,000 feet there is sufficient oxygen to supply the hæmoglobin In ascending to high altitudes the pressure of the air within and without the lungs is the same, but on the heart the action is different The pressure is removed from the outer surface of the heart, while the internal blood pressure remains the same There consequently must be dilatation of the heart walls This, in the speaker's opinion, was the cause of the heart failure under these circumstances

DR B F WESTBROOK, of Brooklyn, thought that the explanation of the author with reference to the effect of high altitudes on the heart is correct, but in the pneumatic cabinet the conditions are different Where the patient inhales compressed air or sits in a rarefied atmosphere and inhales air at the ordinary pressure, there is an absolute or relative increase of pressure within the thorax The heart is therefore submitted to a relatively increased pressure As a matter of practical experience, patients with mitral stenosis or mitral regurgitation with pulmonary congestion can be put in the cabinet with safety He would hesitate very much before putting a patient with aortic regurgitation into the pneumatic cabinet In mitral disease, however, the tendency is to assist rather than exhaust the diseased heart

DR S SOLIS-COHEN, of Philadelphia, said that when the individual goes into a rarefied atmosphere there is a disturbance of the relationship between external and internal pressure, and this disturbance will necessarily bring upon the patient disease The inhalation of compressed air in cases of dilated heart has been recommended by Waldenburg and others He had recently employed this measure with beneficial results in alleviating the dyspnœa and defective circulation due to a dilated heart

Dr James T Whittaker, of Cincinnati, said that the condition met with in a rarefied atmosphere cannot be compared with that met with in the pneumatic cabinet It does not seem possible to exert any mechanical pressure upon the heart in the cabinet The conditions which have been observed admit of easier explanation by a study of the effects on the surface vessels When the pressure is removed from the superficial vessels, the dilated heart propels the blood easier than before This is one of the most efficacious means of treating irregular heart He had used the cabinet for two years and had seen no ill effects from its use

Dr F C Shattuck, of Boston, read a paper on

SOME HOSPITAL CASES OF PHTHISIS, MARKED IMPROVEMENT UNDER GENERAL TREATMENT WITH SPECIAL REFERENCE TO ALIMENTATION

Many of the patients had been exposed to unfavorable hygienic surroundings The treatment employed was devoted largely to improvement of the general condition Search had been made for a specific treatment If the disease is of a parasitic nature it is natural to suppose that such a treatment would be of avail At present no such method of treatment is known There are few individuals to whose lungs, at one time or another, the bacillus does not gain access The fact that certain individuals are affected while others escape, forces us to believe that there is a predisposition to the disease The treatment employed by the author had consisted in relieving symptoms, improving the digestion, and the administration of as much food as the patient could take in the natural way Artificial feeding was not resorted to, but the patient was fed six or seven times a day From two to ten raw eggs with milk were given daily to each patient Alcoholic stimulants were not administered to the patients as a routine treatment, but were used only temporarily for special purposes He had for several years been systematically cutting down the quantity of alcohol used in chronic cases, and had seen no reason to regret it His experience had been that alcohol was not used with sufficient discrimination in chronic cases of disease Beef, milk, eggs, and other nourishing articles are more expensive than alcohol, but, if they can be consumed in sufficient quantity, they are more useful In 1883 the amount expended per patient for alcoholic liquors had been $2 70, while in 1886 it had been only 34 cents The patients received no injury even if they were not benefited by this reduction Eight cases of well marked phthisis were reported in which a decided gain in weight and general improvement resulted from the employment of the plan of treatment above described About sixty cases had been under treatment

Dr E T Bruen, of Philadelphia, read a paper on

GASEOUS ENEMATA

Of the therapeutic measures under the control of the profession, diet, climate and suitable hygiene are of principal importance It is possible by climatic and dietetic treatment to so change the nature of the tissues that they shall not be suitable culture media for the growth of the bacillus of tuberculosis I wish, however, to refer more particularly to the use of the Bergeon method by the injection of sulphuretted hydrogen To antagonize the specific cause of the disease, this method has been a failure so far as my experience goes Since February last I have had under treatment sixty one cases by this method Systematic examinations of the sputa have been made by Dr E O Shakespeare There has been no apparent reduction in the number or change in the character of the bacillus This method should be classed among the methods at our disposal for the treatment of this disease The good effects in my hands have been reduction of temperature, reduction of expectoration, very often a complete suppression of bronchial catarrh, and relief of cough This leads to improved digestion and enables the dietetic treatment to be carried out with great thoroughness Forty four of these cases showed improvement to a certain extent, the average gain in flesh being about five pounds In one half of the cases the temperature has been brought to the normal, while in the remainder, although the temperature has not been brought to normal, it has been reduced two or three degrees In fifteen cases the results have been negative, but in no case did any harm follow the use of this plan of treatment The improvement has been most marked where there is a considerable catarrhal element Those cases in which there has been more or less thickening of the lung, with the general symptoms well marked, wasting, loss of flesh and weight without much rise of temperature, I have found not specially benefited by the injection of gas I have had the opportunity of making a post-mortem in one case which had been subjected to this treatment Although the cavities in the lungs were unusually clean, I did not observe any evidences of cicatrization With reference to the strength of the solution, I have not found strong solutions at all satisfactory The best results have been obtained from a solution of 5 grains of sulphide of sodium with 5 grains of chloride of sodium in 1½ pint of water I have never found it desirable to administer more than 1½ gallon of gas at one time I insisted that the injection be made slowly and that one half to three quarters of an hour should be occupied I have not derived as much satisfaction, in the treatment of the various forms of phthisis to which I have referred, from any method as I have from the injection of sulphuretted hydrogen I have always tested the breath for the presence of sulphuretted hydrogen I have had negative results in at least eight out of every ten cases

Dr S Solis Cohen said that the experience of Dr J Solis Cohen and himself differed in some respects from that of Dr Bruen They had obtained the most decided benefit from strongly impregnated waters The best results were obtained in those cases in which the patient had a decided taste of sulphuretted hydrogen which continued for two or three hours after injection The best effect has been obtained in those cases in which suppuration is about beginning In about 50 per cent of the cases the condition has been greatly ameliorated In another 25 per cent there was slighter amelioration, while in

the remaining 25 per cent there was more or less benefit to certain symptoms He had seen no case in which no results were obtained

DR JAMES T WHITTAKER had for a month used sulphuretted hydrogen by inhalation, having previously employed it for a month by injection He puts the patients in the cabinet and allows them to have all the gas they will take It has produced no unpleasant results in any case The effects obtained have been about the same as those resulting from injection In about one third of the cases there were no results In searching the literature for records of bad results following the use of sulphuretted hydrogen, he found only ten in which a fatal result followed

DR ROLAND G CURTIN, of Philadelphia, stated that it had been recommended by Dr C Wood that the sulphuretted hydrogen be taken by the stomach, using a saturated solution through which carbonic acid has been passed He had tried this in four or five cases, and had had the same effects as from injection

DR F C SHATTUCK had used the sulphuretted hydrogen gas, and in several patients it produced collapse in varying degrees, with weak pulse, nausea, vomiting and headache In several other cases, although the treatment was well tolerated, it produced no good effect In one case of asthma with chronic bronchitis and emphysema thirty four injections of the gas were given While the treatment did not disturb the patient, it did no good With the use of the gas was combined the administration of iodide of potassium and other remedies, and the patient recovered in about the same time as on a previous occasion when the latter remedies were given and no gas used

DR B F WESTBROOK, of Brooklyn, read a paper on

THE LOCAL TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS

The methods of treatment which had been employed were the direct introduction of coarse sprays, the use of the Evans inhaler and the use of the pneumatic cabinet In the treatment of phthisis the best results are attained in the early stages of the disease, or where the disease, although further advanced, is limited to a small portion of the lung The use of sprays is beneficial only in so far as we desire to treat the coexistent bronchitis or cavities connected with bronchi of the second or third order In incipient phthisis with very little bronchial catarrh, local treatment is probably of little service These cases are best treated with compressed air In a large proportion of the cases we may hope to render the disease latent The expansion of the lung favors the expectoration of the contents of the smaller tubes and modifies the intra thoracic circulation The sittings should be frequent—every day or every second day Ten minutes is usually sufficiently long for the patient to remain in the cabinet The pressure should gradually be increased up to one half or three fourths of an inch If used cautiously this is the best method for the local treatment of incipient phthisis With the Evans inhaler his results had also been satisfactory

In the treatment of advanced cases the first effort must be to cure or diminish the bronchitis The pneumatic treatment then comes into play This gives better expansion, improves the circulation and alters the action of the trophic nerves In all cases internal medication has been combined with the local treatment The more acute the disease, the higher the fever and the more sudden the onset, the less can we expect to accomplish by treatment In no case diagnosed as acute phthisis did treatment have the slightest effect

---

WEDNESDAY, JUNE 1—SECOND DAY

DR A Y P GARNETT, of Washington, read a paper entitled,

OBSERVATIONS UPON THE SANITARY ADVANTAGES OF TIDE WATER, VA, INCLUDING VIRGINIA BEACH, AS A WINTER HEALTH RESORT

While no official records of the causes of death in this locality have been kept, the traditions of the inhabitants during the past hundred years and the observation of intelligent practitioners practicing in this region, go to show that consumption is very rare In other respects this locality is remarkably healthy The average number of deaths per thousand from all causes during the past six years has been 10 66 The average death rate in other sections of the State is 12 per thousand The author was disposed to attribute some of the benefits which this locality presents to the proximity of the Great Dismal Swamp which has an area of thirty by ten miles covered with cypress and evergreen trees At Virginia Beach the forest comes down close to the sea The atmosphere is remarkably dry, and salt exposed during the day shows no tendency to absorb moisture The average temperature during the winter months is considerably higher than other places along the coast As compared with Atlantic City, we have the following figures

	Virginia Beach	Atlantic City
January, - -	34 6°	30°
February, -	39°	29°
March, - -	45°	39°

DR A L LOOMIS, of New York, read a paper on

EVERGREEN FORESTS AS A THERAPEUTIC AGENT IN PULMONARY PHTHISIS

It has long been known that similar climates as determined by geographical and meteorological conditions have different therapeutic effects That there is some relation between the development of organisms and atmospheric conditions is becoming more and more apparent We know that cold and high altitude render the air aseptic, but the degree of cold and the height required is so great that clinically it is not possible to derive much advantage from this fact The effect of a purely aseptic air upon ulcerative processes is not so great as the effect of an atmosphere which is aseptic on account of the presence of antiseptic agents The belief in the good effect of pine forests in cases of phthisis is quite unanimous and the author thought that the clinical evidence in

favor of their beneficial influence in these cases was unquestioned The atmosphere in such regions is not only aseptic but also antiseptic Such an atmosphere contains considerable turpentine vapor and we should therefore expect it to contain a certain amount of peroxide of hydrogen It was the speaker's opinion that the majority of cases of phthisis die, not directly from the lesions of the lung, but from the secondary septicæmia and pyæmia which is set up It is impossible to apply to the ulcerations within the lung the antiseptic washing and dressing that is employed in external lesions, but if an antiseptic atmosphere can be obtained we may hope to counteract the secondary poisoning Such an atmosphere will not destroy the bacilli, but it will accomplish much in the way of arresting the suppurative process It was the opinion of the speaker that the atmosphere in the region of evergreen forests acts in a manner similar to the antiseptic agents which are successfully used to arrest suppurative processes in other portions of the body, and he thought in all probability the active agent was the peroxide of hydrogen resulting from the oxidation of the turpentine vapor While it is not possible for every one suffering with pulmonary phthisis to go to an antiseptic atmosphere it is possible to render the air of any particular locality antiseptic The evergreen forests should be preserved and evergreen trees should be planted in the neighborhood of our houses

Dr S Solis Cohen stated that he had had excellent results in the way of alleviation of symptoms in phthisis by the inhalation of terebinthinate substances, especially where this has been associated with the inhalation of peroxide of hydrogen or oxygen Under these inhalations he had seen laryngeal ulcers cicatrice, especially if they have been previously washed with the solution of peroxide of hydrogen

Dr W C Van Bibber, of Baltimore, read a paper on *The Climate of the Sub-Peninsular Pinellas, Florida*

Dr E L Trudeau, of Saranac Lake, N Y, read a paper on

ENVIRONMENT IN ITS RELATION TO THE PROGRESS OF BACTERIAL INVASION OF TUBERCULOSIS

Environment evidently has an important bearing in reference to bacterial invasion The author proposed to himself the following questions 1 What results ensue when bacillar invasion and unhygienic conditions are made to co exist? 2 Are unhygienic surroundings sufficient to cause phthisis when precautions are taken to exclude the bacillus? 3 Is bacterial infection always productive of tuberculosis when the animal is placed under the most favorable hygienic conditions? In order to answer these questions the following experiments were performed Fifteen healthy rabbits were taken and divided into three sets of five each The first experiment consisted in taking five of the rabbits, inoculating each with a pure culture of the tubercle bacillus and subjecting them to overcrowding in a dark cellar with poor and insufficient food and other unhygienic conditions In the second experiment five rabbits were placed in a box and lowered into a pit dug in the ground, the mouth of the pit covered with earth with the exception of a trap door for the introduction of food, which consisted of one small potato for each animal per day So damp was the air that the box in which the animals were confined was constantly wet The third set of animals were inoculated with the tubercle bacillus and turned loose on a small island where they had abundant sunlight, fresh air and exercise They were daily supplied with wholesome food

The results of the experiments were that four of the first five rabbits died in three months and extensive tuberculosis found The fifth animal was killed at the end of five months and the same condition found The second set of rabbits were all living at the end of four months They seemed to be as active as at the time the experiment began They were then killed and careful examination showed nothing abnormal One of the third series of rabbits died at the end of one month and on examination there was enlargement of the cervical and bronchial glands and tubercles in the spleen The remaining rabbits continued in apparently good health and were killed at the end of four months They were loaded with adipose tissue, the flesh was firm and red, all the organs were normal and even the seat of the punctures could not be made out These experiments confirm the theory that the production of tuberculosis is a most complex process Although the environment may bear but the relation of a predisposing cause to the microbe invasion, it is nevertheless a most potent factor in determining the future and final results of the disease, and while we may not underestimate the pathogenic properties of the bacillus, the effect of environment upon the vitality, is a factor which must not be ignored

---

AFTERNOON SESSION

Dr A C Peale, of the U S Geological Survey, Washington, presented a *Classification of American Mineral Waters*

Dr F F Smith, of St Augustine, Fla, read a paper on

ST AUGUSTINE, FLA, AS A WINTER HEALTH RESORT

He described the geographical and climatic conditions existing in St Augustine An abundance of pure water is obtained from sixty artesian wells This water is charged with sulphuretted hydrogen Drinking water is obtained by means of cisterns A complete system of sewers is now being introduced These will be flushed by the waste water from the artesian wells The average temperature during the winter months of the past ten years has been as follows November, 63°, December, 57, January, 55°, February, 58°, March, 61°, April, 67° The average number of rainy days during the winter months for the past ten years has been 33, but on 19 of these occasions the rainfall was at night so that there was really only *14 rainy days*

The following papers were read by title

An Invalid's Day in Colorado Springs, by Dr S E Solly, Colorado Springs, *The Climate of Southern California*, by Dr H S Orme, Los Angeles, Cal,

Pas Christian, Mississippi, as a Health Resort, by Dr Chas LeRoux, Pas Christian

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted Dr A L Loomis, of New York, (with Dr F Donaldson, Sr, of Baltimore, as alternate) was appointed as the representative of the Association to the Committee on the Congress

OFFICERS FOR THE ENSUING YEAR

President —Dr A L Loomis, New York

Vice-Presidents —Drs A P Y Garnett, Washington, and James T Whittaker, Cincinnati

Sec'y and Treas —Dr James B Walker, Philadelphia

Council —Drs E T Bruen, Phila , J H Tyndale, New York, F H Bosworth, New York, F C Shattuck, Boston, and R G Curtin, Phila

The Association then adjourned

FOREIGN CORRESPONDENCE

LETTER FROM GOETTINGEN [1]

Surgical Tuberculosis — Tuberculosis of Ribs, of Knee, of Elbow—Resection of Hip—Koenig's Success with Tuberculosis—Iodoform—Carcinoma of the Rectum—The Germ of Erysipelatoid of the Fingers —Merkel

Professor Koenig spent a whole forenoon in showing the most interesting cases of surgical tuberculosis and in describing the different affections and explaining their treatment A number of cases of tuberculosis of the ribs were shown, among them one where nearly an entire rib had been removed When tuberculosis selects a rib, and this is rather a frequent point of localization, it appears usually as a central lesion primarily extending by continuity along the central cancellated tissue and towards one or both surfaces of the ribs, where the periosteum is destroyed and the disease extends to the contiguous soft tissues, giving rise to diffuse abscess in the external wall of the chest, where it extends in a superficial direction, and to the formation of peri pleuritic abscess, when the process travels in the direction of the pleura If such abscess have opened spontaneously or have been incised extensive and sinuous fistulous tracts are formed, which frequently renders the detection of diseased bone, by probing, difficult or impossible Treatment by simple scraping seldom leads to a permanent cure, as it is almost impossible to reach all of the diseased tissue with a spoon The only treatment which can be relied upon is to expose the rib freely by an incision and to follow the disease until healthy bone is found and then to excise the entire thickness of the rib Abscess cavities and fistulous tracts must be laid open freely and thoroughly scraped A case was shown where the fourth rib in a young woman was the seat of the disease, and where numerous fistulous tracts lead underneath the mamma where, in order to expose the diseased rib freely, the entire breast was loosened from its attachments to the chest and reflected, after the removal of the diseased tissues it was replaced and fixed with sutures The case is now progressing favorably

An exceedingly interesting pathological condition in tubercular joints was described and illustrated by specimens and drawings on the blackboard It related to cases in which the tubercular process is primarily located near an articular cartilage, and where at a corresponding point in the joint a plastic exudation takes place, and which, after it has become fully organized, protects the remaining portion of the joint against infection, as for an indefinite period of time and perhaps permanently this plastic wall limits the extension of the disease It is a spontaneous effort towards retardation of the process, and may even result in a permanent cure

In children suffering from tuberculosis of the knee joint Koenig resorts to arthrectomy and careful removal of tubercular foci from the articular extremities with the sharp spoon In adults he prefers typical excision He showed two female patients, aged respectively 63 and 65 years, to prove that old age is no contraindication to excision of tubercular joints Both patients were suffering at the same time from pulmonary tuberculosis One of them had undergone excision of a tubercular knee-joint five weeks previously, and the wound had nearly healed under two dressings without suppuration, at the same time the general health had materially improved The second case was one of tuberculosis of elbow joint, followed by the formation of an immense articular abscess in a greatly emaciated phthisical woman, where the object of the operation was more for alleviation than cure, but where, against all expectations the wound healed in a remarkably short time without the formation of a drop of pus Although in this case the general condition did not improve, the increased comfort has more than compensated the patient for the risk she assumed It is difficult to conceive of anything more satisfactory than the prompt healing of such immense wounds under such unfavorable local and general conditions I doubt if any one but Koenig can show such results After excision of the elbow joint he does not resort to passive motion until five weeks after the operation, when the forearm is flexed at right angles with the arm, and in this position is immobilized for another week or two, after which time regular passive motion is made

In excising the hip joint he makes a long straight incision over the centre of the greater trochanter down to the bone, after the joint has been reached the upper rim of the acetabulum is always removed with a chisel, so as to afford better access to the joint With a chisel the trochanter is divided into three parts in the line of the axis of the bone, the central portion is the thickest, and its upper portion is cut off so as to secure direct drainage of the joint after the lateral portions have been replaced and retained with a few sutures Through such an opening the head and neck of the bone can be readily removed, and the acetabulum becomes accessible

[1] By permission of Drs Fenger and Senn

for operative procedure should the local conditions warrant such a step, while through the defect in the great trochanter efficient drainage could be established The whole after-treatment consists in rest in bed with extension by weight and pulley in abducted position for five weeks After this time the patient is allowed to walk on crutches and extension is applied only during night for at least a year

Since I have seen the numerous patients in Koenig's klinik, where a few weeks after the operations the wounds were either entirely healed or only a superficial granulation surface remained, I have become convinced that the numerous failures in my own practice and the practice of other surgeons were due to imperfect removal of diseased tissues, especially in the acetabulum and the capsule Koenig attacks these structures boldly and fearlessly with his chisels and large spoons, and does not close the wound unless he has satisfied himself that the object of the operation, the removal of the granulation tissue, has been accomplished Other surgeons will do well to follow his example

That iodoform is used after these operations is unnecessary to mention, as Professor Koenig has not lost his faith in the anti bacillary effect of this drug You are undoubtedly aware that two of your countrymen have recently tried to prove that iodoform has no antiseptic properties whatever This is a strong claim, as it comes in conflict with the practical experience of thousands of surgeons who for several years have had unlimited faith in its antiseptic qualities, and have been pleased with the results The communication from Copenhagen caused quite a commotion among the German surgeons, as the claims were based on results obtained from experiments, and no one doubted the reliability or sincerity of its authors Numerous careful experiments were made in Berlin by de Ruyter, who presented the results of his investigations to the German Congress of Surgeons at their last meeting, wherein he showed to the satisfaction of all present that while iodoform may not prevent germ growth directly, it has a decided antiseptic action, as when it is brought in contact with ptomaines a chemical change takes place which destroys the toxic effects of the products of the germs In the discussion after the reading of this paper Professor Bruns said that iodoform possesses direct anti-bacillary properties, and in support of this assertion states that he had treated fifty-four cases of tubercular abscess by injecting a mixture of alcohol, glycerine and iodoform after evacuating the pus, and out of this number forty recovered As an additional proof of the anti tubercular effect of iodoform, he has observed by careful examination that a few weeks after an iodoform injection into a tubercular abscess, the bacilli had completely disappeared Volkmann expressed himself as perfectly satisfied with iodoform, and said that in the face of such uniform favorable results we had no right to abandon it as an antiseptic

I have had an opportunity to satisfy myself, in the private laboratory of Professor Socin of Basle, which is in charge of Dr Garrè, his private assistant, that something must have been wrong in the Copenhagen experiments Dr Garrè showed me a number of gelatin plates which had been exposed to an iodoform spray and subsequently inoculated with different pus microbes, and which remained perfectly sterile Dr Garrè attributed the antiseptic quality of iodoform entirely to the iodine which it contains, and consequently places great stress on using a reliable preparation, carefully kept in a dark place

Prof Koenig has had an extensive experience with cases of carcinoma of the rectum, and has come to the conclusion that when the disease has extended high up it is better not to resort to desperate measures with a view to its removal, but prefers now, in such cases, to make an inguinal colotomy by dividing the bowel completely, emptying and closing the distal end and stitching the proximal end into the wound. This operation affords great relief, prolongs life, and is preferable to the more doubtful results obtainable by extirpation of a high rectal cancer I believe Koenig only echoes the sentiments of all prudent and conscientious surgeons on this subject There is a limit to radical measures in this as well as in malignant affections of other organs

Professor Rosenbach has finally succeeded, after a long and patient search, in demonstrating the germ of a rather frequent but heretofore obscure lesion, *erysipelatoid of the fingers* This disease is a specific dermatitis and always results from inoculation Butchers, cooks, in fact persons handling game, are most frequently affected by it The appearances of the skin resemble true erysipelas, but the affection remains circumscribed, never gives rise to constitutional symptoms, and disappears spontaneously after two to four weeks The germ, which is invariably present, belongs to the class of algæ, grows readily upon gelatine culture, and when inoculated always produces the same disease

One of the evenings in Gottingen I spent at the house of Professor Rosenbach, where I met Professor Merkel, the anatomist, and the house staff of the surgical clinic A superb dinner was served, and although our host does not enjoy the weed, he had made special provision for this occasion, and the best brands of imported cigars were freely distributed during the evening I visited Professor Merkel the next morning at the Theatrum Anatomicum and examined the splendid collection of skulls, Langenbeck's beautiful dissections of vessels and nerves, and the beautiful specimens of injected lymphatics made by Teichmann for his classical work on the "Anatomy of the Lymphatics " The table in the lecture-room is the same as was used by my distinguished countryman, Haller It is made of oak wood, and although not as convenient as the dissecting tables of more modern construction, it answers every purpose, and it is to be hoped that it will serve the same useful purpose for many generations yet to come The sight of such a venerable structure brings up many memories of the past, as a number of the greatest anatomists have stood at its head, and many of the most distinguished men who have gathered around it for several centuries have here laid the foundation for their successful career Professor Merkel is a son in law and successor of the famous anatomist Henle, and is a

worthy follower of the long line of distinguished anatomists who have preceded him He is now writing an extensive work on surgical anatomy which presents certain features which are destined to make it the most useful text book on this subject

The crowning point of my visit to this old seat of learning was a dinner given by Professor Koenig in one of the apartments of the hospital shortly before my departure, to which Professor Rosenbach and the house surgeons were invited Toasts were drank, views exchanged until the cruel town clock reminded us that the hour for leaving had arrived I parted from the band with a distinct promise that we should meet again "in the land of the free and the home of the brave" Very sincerely yours, N SENN

DOMESTIC CORRESPONDENCE

THE METRIC SYSTEM

Dear Sir —On May 8, 1872, it was resolved in the Section on Materia Medica and Chemistry "that the inclusion of the decigram and of the cubic centimetre in the list of officinal weights and measures is considered as desirable, and tending to the advance of medical science" On May 5, 1875, the American Medical Association adopted a resolution offered by Dr Seguin, to appoint delegates to advocate in Europe the unity of clinical observation—to invite European societies to concert a plan of *uniformity* of *methods, instruments, scales, and records of clinical observation* The plan embraced the unity of clinical thermometers, thermometric scales, charts, etc, a uniform graduation of the sphygmograph, myograph, spyrograph, æthesiometer, dynamometer, globulimeter, ophthalmoscope, thermoscope and other instruments of precision used in diagnosis, etc On June 7, 1876, Dr Seguin, in his report, in the name of the commission appointed the year before, says This is not only a question of pride for the Association, it is one of justice to the American physicians at large"

On June 7, 1878, the following communication from the Medical Society of the State of Pennsylvania, was entered on the minutes of the Association

At the annual meeting of this body held in Pittsburgh, May, 1878, it was unanimously

Resolved, That the Medical Society of the State of Pennsylvania, recognizing the advantages of the metric system from its universality, simplicity, and scientific character, does recommend the use of the same to the members of the Society, and urges them to familiarize themselves with it, and to advise their students to use it exclusively when they commence their medical career

Resolved, That in all communications made to this Society in which reference is made to weights and measures, the metric system only should be used

Resolved, That the Secretary of this Society is instructed to bring this action to the notice of the American Medical Association at its next meeting, and urge upon that Association a similar action

At this same meeting of the Association, Drs Marion Sims, T M Drysdale and E Seguin were continued as commissioners and delegates to foreign medical organizations to *urge* the question of uniformity in medical observation, etc Two days before this the following was adopted by the Section on Medicine

Resolved, That this Section, recognizing the value of the metric system for its uniform, international, indestructible, generally applicable, convenient, simple, safe and scientific character, hereby recommends to all physicians the use of the same in their practice, and in their writings and teachings

At the annual meeting of the Association in 1879, the Association took the following action in regard to the matter

Resolved, That the American Medical Association adopts the International Metric System, and will use it in its Transactions

At the annual meeting in 1880 the Executive Metric Committee appointed in 1879, recommended (1) the teaching and practice of the metric system in Medical Colleges, Clinics, Dispensaries, etc, (2) that the Association charge its Executive Metric Committee with the duty to report annually on the above institutions which teach, and those which do not teach the metric system

These recommendations were adopted

The foregoing may seem to be ancient history, but it is sometimes useful to read such history in order to see what it has taught Three or four years ago there was a warm discussion on the metric system in the *Medical News*, in which the system was upheld and adversely criticised—but without one good argument being made against it And as yet no one has been able to discover one single fault in the system Of the civilized peoples of the world the English and Americans are the only ones who still adhere to grains, drachms, scruples and ounces For the present discussion it matters little whether the physician writes his prescription in scruples or portions of a ton, provided his chirography be so good that the druggist will not mistake his signs (and how many do write so clearly?) But what the readers of our literature demand, and what scientific accuracy demands, is that we shall use the metric system, that we shall no more read, and speak of in our writings, grains and ounces, inches and feet, Fahrenheit degrees, cubic inches and feet, or any other system of weights and measures than the metric The amount of medical literature that is literally poured into this country is enormous, and with the exception of some of that which comes from Great Britain and her colonies, every weight and measure is expressed in the metric system, save in a few provoking cases (which find their counterpart here) in which a tumor is said to be as large as a nut or a seed

It has been said that even if the metric system is used by "foreigners" the quantities should, in our literature, be translated into the drachms of our daddies And this is an example of the way such must be done, Lewin's sublimate injection for syphilis, is

Corrosive sublimate	0 24 or gr iiij 11
Distilled water	30 or ʒvij ½

Another solution (Rosenthal's) is

Corrosive sublimate	024 or gr 5 16
Glycerine (heated)	4 or ʒj
Water, q s ad	15 or ʒiij ℈ij

The English and American system seems to com

pare as favorably with the metric as the Chinese does with our grains and drachms The metric system is not "foreign", it is scientific, and science knows nothing of nationality Are we waiting for England? Why should we not take the lead? In fact England is already ahead of us in the use of the metric system

Suppose it is a linear measure If an instrument of precision be 2 cm long it must be translated 4 5 inch If the diameter of a tube be 3 mm we must say 03937 inch if we wish to be precise, and the matter becomes ridiculous when we translate the size of microscopic objects from micromillimetres to fractions of an inch—for there is just as much reason to translate micromillimetres as centimetres or kilometres

If a "foreign" writer speaks of one litre we must write 1 0565 quart in order to be exact, if cubic centimetres be the measure we must use fractions of cubic inches, or decimals

In recording thermometric measurements the inconvenience is not so great, as we can always easily do away with fractions by using decimals—yet we not infrequently see the fractions used The chief inconvenience is that in order to read temperature charts, in other languages, intelligently we must constantly bear in mind two separate scales The barometers used for accurate scientific measurement are graduated in millimetres, and there are no decimals as in case of those commonly used in this country

The truth concerning the neglect of the metric system in this country is that, in the first place it is not properly taught in schools, nor are decimals properly taught, in the second place, it is a little trouble to learn something new and strange, and our fathers got on pretty well with their system I will venture the assertion that there are not half a dozen good chemists in this country or any other who use the apothecary's weight in their work All books on examination of urine, etc, are written entirely in the metric system If there were no other reason for adopting the metric system, the fact that it is used by the large majority of medical and scientific men —and has been found by them to be uniform, generally applicable, convenient, simple, safe and scientific in character—would be alone sufficient

Very truly, WM G EGGLESTON

Chicago, July, 1887

INTERNATIONAL CONGRESS

SECTION OF DERMATOLOGY AND SYPHILOGRAPHY

The following list of papers proposed to be read in the Section of Dermatology and Syphilography of the International Medical Congress, comprises those received previous to July 1, 1887 A number of papers have been promised by prominent European writers but the titles have not yet been received

1 Lupus Lymphaticus, with drawings, by Mr Jonathan Hutchinson, London

2 Das Seborrhoische Ekzem, by Dr P G Unna, Hamburg

3 Hydroa and its relations to Pemphigus, Herpes, Dermatitis Herpetiformis (Duhring,) Impetigo Herpetiformis (Hebra), Herpes Gestationis, by Dr T Colcott Fox, London As an introduction to a general discussion of the subject

4 Treatment of Syphilis by injections of insoluble mercuric salts, by Dr H Watraszewski, Warsaw

5 La lepre observée à Constantinople, by Dr Zambaco, Constantinople

6 L'elephantiasis des Arabes chez les enfants, by Dr Moncorvo, Rio de Janeiro

7 A new method of treating diseases of the skin locally, by Dr Valentine Knaggs, London

8 Einige trophoneurotische Gefassaffectionen, by Prof E Schwimmer, Budapest

9 Sur le mycosis fongoide d 'Alibert Nouvelle communication clinique avec recherche de microorganismes, by Prof Tomasso de Amicis, Naples

10 Electrolysis in Dermatology, by Dr J N Bloom, Louisville

11 On the occurrence of Ulcers resulting from spontaneous Gangrene of the Skin, during the later stages of Syphilis, and their Relations to Syphilis, by Dr Herman Klotz, New York

12 Double Comedo —An Anatomicopathological study, by Dr A H Ohmann-Dumesnil, St Louis

13 Erythematous Lupus of the Hands, by Dr Ohmann Dumesnil

14 A new method of treating Favus and Herpes Tonsurans, by Dr H J Reynolds, Chicago

15 Area Celsi, by Dr A Ravogli, Cincinnati

16 Lupus Erythematosus, by Dr A Ravogli

17 A contribution to the Knowledge of Impetigo Herpetiformis (Hebra), by Dr Joseph Zeisler, Chicago

18 Rectal alimentation in diseases of the Skin, by Dr J V Shoemaker, Philadelphia

19 Vaccination during the incubation period of Variola, by Dr William Welch, Philadelphia

20 Studies in Hirsuties, by Dr G H Rohé, Baltimore

21 A unique case of progressive Melanosis of the Skin, with exhibition of subject, by A R Robinson, New York

22 The pathology and therapeutics of Alopecia Areata, by A R Robinson —As introduction to a general discussion of the subject

A R ROBINSON, President of Section

REGISTRATION BLANK

"The Congress will consist of such members of the regular medical profession as shall have registered and taken out their tickets of admission, and of such other scientific men as the Executive Committee of the Congress shall deem it desirable to admit" The fee has been fixed at ten dollars Each member of the Congress will be entitled to a copy of the Transactions —*Rules of the Executive Committee*

Those about to register will please read and give attention to the following directions to secure accuracy in the list of members of the Congress, and, to prevent mistakes therein, it is especially requested that all proper names of persons and places shall be

written distinctly and in full, and without abbreviations in any case (*For example* Instead of J W Taylor, Phila, Pa, it should be written John Warren Taylor, Philadelphia, Pennsylvania, etc, etc)

By order of COMMITTEE OF ARRANGEMENTS

Register No

FORM TO BE FILLED UP BY APPLICANT FOR MEMBERSHIP IN THE CONGRESS

Data Required

Name in full
Post-Office Address
If in a city, give also street and number
If in the country, give also name of the county
State
Province
Country
If a Delegate, state from what country or society
Practice general or special
If special, name the branch

CONCERNING A COMMEMORATIVE MEDAL

As former International Medical Congresses have been commemorated by suitable medals, it is proposed (should a sufficient number be subscribed for) to have one of good size and proper design struck for the IX Congress A medal with the head of George Washington on the one side and the seal adopted for the Congress on the other, would doubtless be appropriate The medal of the London Congress had the bust of the Queen on one side and the seal of the Congress on the obverse, and cost one guinea Such a medal, well executed in bronze, will cost us five dollars Those approving the project and desiring such a medal will deposit five dollars with the treasurer, who will give a receipt for the same, and deliver the medal in proper time, if struck

Blank form to be filled

Name in full
Post Office Address
Number of medals subscribed for

If from any cause the medals should not be struck, the money will be returned to subscribers

---

THE INTERNATIONAL MEDICAL CONGRESS —We copy with full endorsement, the following from the July Number of the *Alienist and Neurologist* —[ED] Before another issue of this *Journal* shall have gone forth to its readers over the world, the Congress will have met in Washington, received the cordial fraternal welcome America's physicians are preparing for it, finished its scientific work for the year and cemented anew the bond of friendship and fraternity existing throughout the world among all true physicians

A few who invited the Congress may not be there to greet its members, but we hope they will

We hope the few individual declarations of this kind will be reconsidered and revoked At all events the Congress will be heartily received by the American profession as a body The army will be there to honor them, though a few deserters may be in the rear, and a few "wounded in spirit"

But by September we hope to see all the wounded restored to the ranks and all the deserters from the camp brought back, not in ambulance or chains and under guard, but cheerfully returning (led by silken cords of love, as it were,) to welcome to our common country our common friends, who have been invited to accept the hospitality of our common household

We will put our family jars in the closet where we keep our skeletons (if we have any on hand in September), and set our best viands on the table We will lock that closet and bury that key or throw it into the sea, and hang out the latchstrings to our hearts and homes, as Americans are wont to do when guests whom they esteem come to their doors

Americans know how to make up after a war as well as how to fight This the world knows We are not fighting over who shall run the Congress now but for funds to run it hospitably and creditably to the American good name for cordial hospitality

Send on your funds, gentlemen, belligerents, to the finance committee, and your swords shall be turned into knives and forks and something for them to work on, and you shall make plowshare furrows into the affections of our coming guests, and pruning hooks to cut off the asperities engendered by the incipient late lamented unpleasantness among ourselves

Everybody is going to the Congress, and everyone is going there in good humor too

---

BRITISH MEMBERS OF THE CONGRESS —The following members with ladies will sail for America to attend the Congress

On the "Germanic" (10th August) will sail Mr and Mrs Th Halliburton, Dr and Mrs W D Halliburton, Misses M and T Halliburton, Dr and Mrs W H Woodruff, Dr and Mrs Grady Hewitt, Dr and Mrs C D F Phillips, Misses Phillips, Dr L Landolt

On the "Adriatic" (August 17) Dr and Mrs W Bowman Macleod

On the "Britannic" (August 24) Lennox Browne, Esq, London, G J Hutchinson, Esq, London, Dr Grant Bey, Cairo, W D Spanton, Esq, Hanley, Dr Boyd Joll, Liverpool, Dr Eddowes, Market Drayton, H Valentine Knaggs, Esq, London, Dr S Brown, Dr Foster McGeogh, Dr Parkinson, Comegys Leach, Dorset, Alfred Aplin, Esq, Nottingham, Dr Dolan, Halifax

These are but a few to sail by White Star Line I expect a large British contingent will attend

(Signed) T M DOLAN, M D

MISCELLANEOUS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U S ARMY, FROM JULY 16, 1887, TO JULY 22, 1887

By par 43, S O 162, A G O, July 15, so much of par 1, S O 156 c s, A G O, as directs Capt Jno de C W Gardiner, Asst Surgeon, U S Army, to report for duty at Ft Washakie, Wyo, is revoked

Capt R Barnett, Asst Surgeon, sick leave still further extended six months on account of sickness S O 162, A G O, July 15, 1887

By par 42, S O 162, A G O, July 15, so much of par 1, S O 156 c s, A G O, as relieves Capt Geo H Torney, Asst Surgeon, U S Army, from duty at Ft Monroe, Va, is revoked

Capt A W Taylor, Asst Surgeon, now at Ft Laramie, Wyo, is ordered for temporary duty at Ft Robinson, Neb S O 162, A G O, July 15, 1887

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDING JULY 23, 1887

Surgeon C S D Fessenden, granted leave of absence for thirty days on account of sickness July 18, 1887

P A Surgeon F W Mead, granted leave of absence for thirty days July 19, 1887

P A Surgeon H W Yemans, granted leave of absence for thirty days July 23, 1887

P A Surgeon S D Brooks, promoted and appointed P A Surgeon from July 1, 1887 July 21, 1887

Asst Surgeon J H White, to proceed to Washington, D C, as escort to an insane seaman July 18, 1887 Ordered to examination for promotion July 23, 1887

Asst Surgeon R B Watkins, leave extended fourteen days on account of sickness July 20, 1887

Asst Surgeon G M Magruder, to proceed to Galveston, Tex, for temporary duty July 21, 1887

ADDRESSES

INTRODUCTION TO MEDICAL JURISPRUDENCE

Address delivered at the Thirty Eighth Annual Meeting of the American Medical Association, June 10, 1887

BY ISAAC N QUIMBY, M D,

OF JERSEY CITY, N J

CHAIRMAN OF THE SECTION ON MEDICAL JURISPRUDENCE

It is not a little remarkable that, while medical jurisprudence is but a new comer in the schools, and only one year ago received its first recognition as one of the legitimate subdivisions of the working scope of the American Medical Association, its origin may be traced to the very beginning of established governments Among the Hindoos as, subsequently, among the Israelites, Greeks and Romans, jurisprudence appears to have engaged the attention of lawgivers from the earliest period of which there is any record It is allied to and coordinate with medicine, but in the use of this comprehensive word medicine (preventive and curative), jurisprudence for the prevention of disease far antedates the use of remedies for curing it Measures for the protection of health, long before they were codified, were first devised and intelligently applied—it scarcely seems necessary to say in this presence—by priests, who, in the exercise of their functions, laid the foundation of medical jurisprudence by a sacerdotal jurisprudence which, in some things, has not been improved upon in the lapse of centuries

Far back in the history of mythology we learn that, while the Babylonians, Chaldeans and other ancient nations had no physicians, in the temples of Canopus and Vulcan, a skilled priesthood had systematic rules for the protection of the public health and regulating regimen To these regulations, in many particulars, a resemblance of the Mosaic ceremonial law is traceable, and finally, in the progress of knowledge, the Levitical code, comprehending regulations concerning food, ablutions and other purifications, the segregation of persons affected with contagious diseases, and the disposal of excreta, are given with such precision as to justify the designation of the Mosaic record, as the earliest code of jurisprudence for the protection of health of which we have any knowledge Herodotus gives a history of this code more in detail According to him the Egyptians had laws regulating marriages and the relation of the sexes, making distinctions in the nature of wounds, whether mortal, dangerous or otherwise, with reference to penalties, prescribing modes of embalming and burying the dead, and in many other respects comprehending a system of sanitary and criminal police scarcely less perfect than that which exists among enlightened communities at the present day

Among the Greeks, Hygeia, the Goddess of Health, was, in like manner, in the foreground of medicine. The Asclepiadæ or priest-physicians who worshipped at her shrine, at the first, wholly confined their advice to preventive medicine, dietetics and hygiene, and Hippocrates, their descendant, taught that

"Whoever wishes to investigate medicine properly should proceed, in the first place, to consider the seasons of the year, and what effects each of these produces (for they are not all alike, but differ much from themselves in regard to their changes) Then the winds, the hot and the cold, especially such as are common to all countries, and then such as are peculiar to each locality We must also consider the qualities of the waters, for as they differ from one another in taste and weight, so also do they differ much in their qualities In the same manner, when one comes into a city to which he is a stranger, he ought to consider its situation, how it lies as to the winds and the rising of the sun, for its influence is not the same whether it lies to the north or the south, to the rising or setting sun These things one ought to consider most attentively, and concerning the waters which the inhabitants use whether they be marshy and soft, or hard and running from elevated and rocky situations, and then if saltish and unfit for cooking, and the ground, whether it be naked and deficient in water or wood, or well watered, and whether it lies in a hollow, confined situation, or is elevated and cold, and the mode in which the inhabitants live, and what are their pursuits, whether they are fond of drinking and eating to excess, and given to indolence, or are fond of exercise and labor, and not given to excess in eating and drinking

"From these things he must proceed to investigate everything else For if one knows all these things well, or at least the greater part of them, he cannot miss knowing, when he comes into a strange city, either the diseases peculiar to the place, or the particular nature of common diseases, so that he will not be in doubt as to the treatment of the diseases, or commit mistakes, as is likely to be the case provided one had not previously considered these matters. And in particular as the season of the year advances, he can tell what epidemic diseases will attack the

city, either in summer or in winter, and what each individual will be in danger of experiencing from the change of regimen For, knowing the changes of the seasons, the risings and settings of the stars, how each of them takes place, he will be able to know beforehand what sort of a year is going to ensue Having made these investigations, and knowing beforehand the seasons, such a one must be acquainted with each particular, and must succeed in the preservation of health, and be by no means unsuccessful in the practice of his art And if it shall be thought that these things belong rather to meteorology, it will be admitted, on second thought, that astronomy contributes not a little, but a very great deal indeed, to medicine "[1]

He next proceeds with the consideration of details based upon the application of the essential knowledge for the successful practice of medicine foreshadowed in this quotation But no union of the principles of law on medicine followed the way so clearly opened by Hippocrates

Lycurgus, who lived eight centuries B C, and Pythagoras, three centuries later, both taught that medicine was a branch of legislation, but so little was known of medicine in Greece that those lawgivers attached no importance to it The sick were regarded as burthensome and efforts to heal them, except of such disabilities as were contracted in the service of the State, were regarded as detrimental to the public welfare And of children, only the strong and well formed were allowed to live, the weak or deformed were exposed to die on Mount Taygetus At the age of 7 years boys were taken from their parents and educated by and for the State, which subjected them to the severest discipline, hence the most robust only survived The laws of Lycurgus and his disciples were so thoroughly implanted on the mind of the State that, during several centuries, while the chief concern was to secure a robust population capable of bearing arms, the people were thoroughly imbued with the doctrine that the best way of perfecting the human species was the barbarous practice of abandoning delicate infants and rearing only those which proved capable of withstanding the severest hardships Even Plato, who had the benefit of the wisdom and philosophy of Hippocrates, taught that children with hereditary diseases should be left to chance for their future development How to provide for the health of cities and camps, appears to have been the full extent of their medical law, notwithstanding the advent of Hippocrates

In Rome, the earliest medical laws of which there is any explicit record were enacted during the reign of Numa Pompilius, contemporary with the laws of the Spartans originating with Lycurgus, to protect the life of an heir, by requiring medical assistance to be summoned in all cases of difficult labor, and forbidding the burial of a pregnant woman until the fœtus should first have been extracted There is no other record of importance until a dozen centuries later, during the reign of Justinian, in the early part of the sixth century of the Christian era, when the controlling influence of Greek philosophy and Greek medicine had become so pronounced that in the *Pandicts* or Codex Justinianeus, various titles are arranged as referring to crimes, physical deformities and questions of legitimacy, with instructions to the courts not to be guided by the judgment of living physicians, but to form their opinions exclusively *"upon the authority of the most learned Hippocrates"* And this in the face of the fact that an *archiater* or State Physician, who was an integral part of the civil government, and who was both physician to the court and the acknowledged head of the medical profession, must have attached to his opinion great weight with the judges, notwithstanding the institutional reverence for Hippocrates

In the sway of human passions and barbarous customs which prevailed in Europe during the "dark ages," the only medical laws of which we have any distinct account were for the prevention of the spread of infectious diseases, at Venice, A D, 1127 But specific quarantine regulations were not established until more than two centuries later, by Viscount Bernabo January 17, 1374 These regulations, however, are scarcely worthy of the prefix medical, inasmuch as they were under the administration of priests who were directed to examine the diseased, and point out to special commissioners the persons infected under penalty of being burned alive And only a few years later, the same ruler forbade the admission of people from infected places into his dominions, on pain of death Venice at the time was the leading commercial city in the world Hence Bernabo's example was imitated in numerous places during his lifetime, insomuch that the priestly authorities professed in most cases to trace the outbreak of the plague to the arrival of some ship, and commercial cities in the south of Europe were wellnigh closed against navigators, while local filth was reeking its deadly vapors, and consequently the plague continued to prevail till exhausted for the want of subjects

Bills of health were also first instituted at Venice, during the reign of plague, and first made obligatory in England in 1636 England, however, followed close at the heels of Venice in the institution of quarantine, at Gloucester, as early as 1348 Other cities and towns followed, with independent regulations, but no general laws were enacted for its enforcement until during the reign of James I, July 30, 1603

For a just appreciation of the contemporary neglect of municipal filth, the prevalence of filth diseases of every kind under the collective name of "plague," intensified by the quarantines, during the dark ages, so well described by De Foe and other historians, it is necessary that we should consider the narrow limits of medical knowledge during that period The teachings of Hippocrates were for the time forgotten, or subordinated to the haphazard results of chance in the place of reason, and "law" was the will of rulers who paid homage to ordeals based upon superstition, under the guidance of an ignorant priesthood The literature of the time on demonology and witchcraft forms an instructive chapter in the history of unreasoning governments who, in

[1] Airs, Waters and Places Genuine works of Hippocrates Translated from the Greek, by Francis Adams, M D, Surgeon William Wood & Co Vol 1, pp 156, 157

default of scientific and legal medicine, appealed to the Deity through the ordeals of fire, water and the judicial combat!

The cloud began to lift in the early part of the sixteenth century, under the reign of Charles V Hippocratic medicine had begun to take root The criminal code of the Germanic Empire, enacted by the Diet held at Ratisbon in 1532, comprehends the first appreciation of rational medicine in union with law This justly celebrated code requires that physicians *shall* be called by the courts in all cases where death has been the result of violent means, whether accidental or criminal Among its first notable fruits was the speedy overthrow of most of the dominant superstitions which had fettered the public mind and cost the lives of thousands of innocent people during the immediately preceding centuries Closely following the criminal code of Charles V, numerous heterogeneous ordinances of the Kings of France were formulated into codes and converted into a system of positive enactments In 1606, Henry IV gave letters patent to his chief surgeon authorizing him to appoint two physicians in each town, whose duty it was to report upon all cases of accidental death The office of *coroner*, however, is of more ancient origin, among the Saxons, as early as A D 905 in a charter of King Athelstan The name is derived from the fact that the coroner, as originally constituted, had chiefly to deal with pleas of the Crown, and had, therefore, much more to do with law than medicine, which inquests, at that time, did not involve And even yet, in England, the Lord Chief Justice of the Queen's Bench is the principal coroner in the Kingdom, and may exercise jurisdiction in that capacity in any part of England, though there are particular coroners for every place of importance, and in some counties several It is the only office in England charged with the investigation of crime, and so long as the coroner is not accessible, there is no authority to examine witnesses until a suspected person has been actually charged or accused before a magistrate Hence his functions in England, especially, still appear to have much more to do with law than medicine, though there, as in this country, medical men often fill the office, but rarely any other persons except lawyers, and consequently inquests there are devoid of the odium so common to the office in this country, consequent upon the want of professional competency

In France the office of coroner has continued, as from the first, chiefly medical, and has attached the most importance to medical evidence In 1667, Louis XIV decreed that in all criminal matters requiring reports, courts should be assisted by at least one of the physicians named by his chief surgeon, and of such binding obligation were these ordinances that, in 1680, a decree of parliament set aside judgments of inferior courts because they had been rendered *without* the *intervention of medical experts* Indeed, more weight appears to have been attached to the importance of medical testimony in coroners' cases in France, two centuries ago, than *now obtains* in the United States, insomuch that the office of coroner in this country has fallen into such deserved ill repute as to have been rightfully abolished in some of the States, and supplanted by other and better means of determining the cause of death notably in Massachusetts, by the appointment of *Medical Examiners*

As a branch of special instruction in connection with medicine, medical jurisprudence appears to have been first organized into a science and taught in the medical schools of Germany, in the latter part of the eighteenth century But the first professorships of the science were created in France, in 1792, and in 1803, the University of Edinburgh followed the example But in England no similar chair was established in any college until 1820, sixteen years after it was first taught in a course of lectures in Columbia College, New York, by Dr James S Stringham, then Professor of Chemistry, and annually by the same professor until his death in 1817 He was succeeded by Dr John W Francis, who held the chair until 1826 Meanwhile, Dr Charles Caldwell gave a course of lectures on the same subject in Philadelphia, 1812–13, and in 1815, Dr Theodoric Romeyne Beck was called to fill a similar chair in the Western Medical College, and to him and to his masterly work, first published in 1823, Forensic Medicine, in this country at least, is indebted for having been organized into a concrete science

In the preceding sketch of the application of law to medicine and its outcome, the first points of contact continue to be those of the greatest importance —the preservation of the public health with regard to local and meteorological conditions, regimen and infectious diseases, medical police and medical evidence, laws regulating marriage and the relation of the sexes, distinctions in the nature of wounds with regard to penalties, disposal of the dead, the *preservation* of *fœtal* and infantile life, quarantine and State physicians are the foundation of, rather than stepping stones to, the elaboration of the same subjects in the present advanced stage of medico legal inquiry The full consideration of any one of these subjects would consume more time than we have to devote to them all—to say nothing of their elaboration into side issues of great importance

Referring the bearings of Medical Jurisprudence on State medicine to the Section of this body specially devoted to it What for example could more profitably engage our attention than the preservation of infantile life, which was the special care of the Romans twenty-six centuries ago? Alas! it is doubtful whether we have much improved upon it, or even that of the barbarous Greeks who sacrificed their weaklings only—*fœticide*, at least, without regard to the utmost vigor of health and the imminent risk to the life of the mother, in the United States is *not a crime* Infanticide, at common law consists in the doing of any act whereby the death of an infant child is caused after it is fully born alive It is distinguished, by law, from the killing of a child within its mother's womb, which is known as *fœticide*

When the death of a newly born infant is occasioned by an unlawful act, as distinguished from mere accident or unavoidable casualty, such an act

constitutes the crime of felonious homicide, and may be either murder or manslaughter, according to the circumstances of the particular case In every instance, however, the death must occur after the actual birth of the child, *or no crime is committed* If a person uses means for the procurement of an abortion upon the mother, either by the administration of medicines or by the use of instruments, or in any other way whatever, and the fœtus is destroyed before birth the act is neither murder nor manslaughter, at common law, but only a misdemeanor[1] It is not indictable to procure an abortion with the consent of the woman unless she is quick with child, and quick with child is defined by the law to mean that the period has not arrived when the life of the infant has commenced, a fallacy based upon an old English law, which no longer obtains, that the use of the term abortion, medically, is limited to the expulsion of the contents of the womb before the sixth month of gestation But that law has long since been repealed, abortion under English laws now means the expulsion of the fœtus at any period of gestation, and its procurement is reckoned a felony This ancient, but now exploded theory that life in the fœtus does not commence until the third or fourth month of gestation, is founded upon ignorance and the misconception of facts—and contrary to the revealed truths and investigations of modern science

This fallacious idea that there is no life until quickening takes place, has been the foundation of, and formed the basis, and been the excuse to ease or appease the guilty conscience, which has led to the destruction of thousands of human lives

In physiology a cell or cellule constitutes the origin or commencement of every plant and animal and the elementary form of every tissue, in fact the entire organized human body may be considered to be made up of a congeries of cells, each set having its own life and appropriate functions From these cells the embryo and fœtus is developed This is a truth so well settled that no well informed physician would care to deny it Should we not then assert most positively that the life of the fœtus commences at the moment conception takes place, and therefore the destruction of the fœtus, at any period of gestation, should constitute murder? Abortion is alarmingly prevalent and increasing especially among the higher classes and well to do American women Ladies present themselves to their physicians—with a thousand and one excuses—for getting clear of their offspring And it is a lamentable fact that there are persons who call themselves physicians willing listeners to their earnest entreaties and appeals

I was consulted not long since, by a reputable physician of experience, upon this subject, and he asked this question "Which do you think the greater crime, the production of a miscarriage, upon the repeated and earnest solicitation of the mother, or compel her to go the full period of gestation, with great worriment, and perhaps sacrifice of her life in giving birth to her child?" I replied, "Doctor, what is the object of our noble profession? Is it to save or to destroy life?" He answered, "To save life, of course" Besides, there is more danger in the unnatural and hazardous procedure of abortion, than the natural process of gestation and parturition

The physician's responsibility in this matter is very grave, and they should do all in their power to discourage this prevailing tendency of the times to fœticide, and teach that life commences with conception God forbid that anyone calling himself a physician should be tempted by any appeal however pressing and piteous, or by any fee however large, to become the assassin of the unborn, in any stage of its development I suggest that a special committee be appointed by the Association to report at its next meeting, upon the *criminality of fœticide* and such measures as may be commended for legislative action for its prevention and punishment[1]

The next subject to which I would invite special attention is to the duties commonly exercised by coroners, and the importance of an improved medical police in regard to immigration—with special reference to the detection and prohibition of chronic invalids and insane persons

The Act of Massachusetts creating Medical Examiners in place of Coroners, has already been referred to

The general duties of Medical Examiners in addition to, or instead of coroner's juries, as at present exercised in most of the States of the Union, as summed up by a joint committee of lawyers and physicians of the New York Medico Legal Society a few years ago, are as follows

"To visit and carefully examine the body of any person reported or supposed to have been slain, or suddenly died, or mortally wounded, or been found dead under circumstances requiring inquisition, make an autopsy if it shall appear to be necessary to ascertain the cause of death, and if it shall appear to said examiner that there is no reason to suspect that a crime has been committed, he should be required to make a careful and detailed report in writing in duplicate, of his examination and autopsy, if any, and deliver one without delay to the nearest coroner and the other to the District Attorney of his county, which report should also contain a statement of the probable cause of death, to be duly verified, whereupon he should give the requisite burial certificate, and, in case the person shall appear to have been a stranger, and no relation or friend shall undertake his burial, give orders for such burial at the expense of the county

"In case the examiner shall be of opinion, from such examination, that a crime has been committed causing or contributing to the death of a person, or he shall entertain doubts upon the subject, he should so report in addition to the other matters above suggested, to such coroner and district attorney, and if he should deem it neccessary, call a chemist to aid in the examination of the body, or of substances supposed to have caused or contributed to the death, and such chemist should be entitled to such compensation as the medical examiner shall certify to be reasonable, and no other chemical or medical examination shall be made at public expense

[1] This Committee was appointed, and consists of Drs J N Quimby N J, W B Atkinson, Pa, and W H Byford, Ill

"On receipt of the last named notice and report, the coroner should without delay institute and prosecute an inquest into the cause of such death, and the name or names of such person or persons who shall appear by said testimony to have contributed to said death should be duly certified by said magistrate, and delivered to the district attorney for his action, and in case it shall appear that said person or persons are at large, said magistrate should be required to issue his warrant for their arrest, and bind the witnesses to appear as such before the next grand jury It should be made the duty of any person who may become aware of the death or mortal wounding of any person, requiring view or examination aforesaid, forthwith to notify the nearest medical examiner, and any wilful or culpable neglect so to do shall be adjudged a misdemeanor" (Medico Legal Paper)

I would suggest as an improvement upon this recommendation to entirely dispense with coroners and repeal the laws providing for them, and that, instead, all the duties and powers of the coroner in relation with the district attorney as recommended in this report of the Committee of the Medico Legal Society, be devolved upon the *medical examiner* and district attorney A recent law in Connecticut, requires that all the coroners in that State shall be attorneys at law It is said to have thus far resulted satisfactorily But the superior fitness of medical examiners for the direction of the duties involved, are so self evident in some of the most prominent aspects—for example, in all cases of alleged malpractice, the necessity for the employment of medical experts, the pathology of the subjects of life insurance and insanity—as to leave no room for question This subject, however, is also so important, and yet so indefinite in its relations to the medical profession, I recommend that a special Committee be appointed on the *Duties commonly exercised by Coroners*, to report at the next meeting

Your attention is now invited to the increase of the dependent classes, particularly of the insane The annual report of the State Board of Charities of New York, shows that the increase of the number of the insane for 6 years in that State was 42 per cent —while the increase of population had not exceeded 12 per cent The report states that, in "searching for the cause of this great and steady increase in the number of insane, in the institutions of the State during this period, it fails to find them in the impaired material, social or other conditions of the State likely to induce the disease, and therefore comes to the conclusion that such increase comes almost wholly from the shipment of insane and other enfeebled persons to our shores from different countries of Europe"

Another important fact is, that *while the number of insane and enfeebled persons is increasing in this country, out of proportion to the increase of population*, they are at the same time on the *proportional decrease* in the *United Kingdom and the Countries of Europe* Therefore, I also recommend a Committee be appointed of Medical Police in relation to Immigration, with special reference to the detection of chronic invalids and insane persons, and the necessity for their exclusion

Next, and finally, your attention is invited to the needful medical jurisprudence of a subject, with the baneful results of which medical practitioners are of all other persons most familiar I refer to drunkenness To dwell upon the effects of alcoholic stimulants, medicinally or otherwise, in this presence, would be entirely supererogatory Moreover, all medical practitioners are more or less familiar with the means hitherto tried for the prevention of drunkenness They have all failed because of their indirectness or narrow limits It is after a good deal of close study of the subject and of much that has been written upon it, that I have arrived at what may be considered very radical conclusions by some for whose opinions I entertain a high respect, but I have become so thoroughly convinced that drunkenness, in general, is a wilful act for which drunkards themselves should be held mostly responsible before the law, that I can no longer withhold the expression of my profound conviction that all the efforts to restrict drunkenness by excise laws, the imposition of fines upon the dealers in alcoholic liquors, and the arguments in favor of its being a disease may be of use as an educational basis, yet if great prudence is not taken in discussion these speculative points may result in the promotion of drunkenness instead of abstinence from the use of alcoholic liquors Unfortunately, drunkenness is so common that no person possessed of ordinary intelligence, will deny that he has sufficient knowledge of the intoxicating effects of alcohol without the necessity of putting it to a test in *his own* person And the exercise of the human will is surely not to be sacrificed to the gratification of the passion to drink even under the pressure of heredity tendencies, for physiology teaches that even these may be resisted by the power of the will, and in most cases overcome But to meet the exceptions, I hold that the State and Society is also responsible to a large extent for much of the drunkenness that exists in our midst The first or primary object of the State or National government is the protection of Society What right then has the State in its corporate capacity, to enact any law or system of laws by which, and through which Society is corrupted or injured thereby?

Does not the State, by license laws, enable her agents (the saloon keepers) to establish themselves in every city, town and hamlet, through which means intemperance is encouraged and promoted, thus becoming *particeps criminis* of drunkenness and its sequences by those who have lost their self control Much ingenuity is exercised, and numerous citations are made by the advocates of inebriety as a disease, but they all fail to show that alcohol bears any relation to the particulate or septic cause of disease, which on once being introduced into the human system multiplies and magnifies as do septic poisons generally Be it far from me, however, to contend that the physical structure of the human body is not so subject to the influences of the continuous use of alcohol as to be liable to change and to become diseased, even to the extent of creating a diathesis, or

This Committee was appointed and consists of Drs H O Marcy Mass, J H H Burge N Y, and W W Dawson Ohio

that the progeny of drunkards before any such diathesis is established are not commonly weakminded, and more likely to become intemperate than the children of other persons, but these truths, instead of in any way detracting from, or affording any palliation of the vice of intemperance, add to its enormity and strengthen the proposition to make drunkenness a crime amenable to law

It is of almost daily occurrence that, in the summary of news, may be read under the head of "Whisky's Work," paragraphs such as the following

Thomas Jones was fatally shot by Michael O'Hara, at Portland, on Sunday night Jones was drunk and abused O'Hara

Chicago, January 17 Last night Abram Night and Louis Kratz got into an altercation over a trivial matter in a saloon, which ended in Kratz stabbing Night several times, slashing him terribly Both are young men, respectably connected Night was taken to his home in a critical condition Kratz is in jail They were under the influence of liquor

New York, April 7 This morning about 1 o'clock, a pistol shot was heard by policeman T P, Sixth Avenue, who on hurrying to the spot found James York lying dead on the pavement in front of Patrick Riley's saloon It was the result of a quarrel between the deceased and a crony, named Joseph Burns, both being intoxicated

There is no more reason in calling such crimes "Whisky's Work" than there would be in calling the attempted robbery of Weeks' house in Brooklyn, which resulted in his murder by the convict who is now under sentence of death, "table silver's work,—which the thief was after in the dining room, or than there would be in calling the robbery of a bank, involving may be the death of the banker or a watchman in its defense, "banker's work"

The primary crimes in these cases were in the first series getting drunk, in the second, stealing, murder, the consecutive crime in both It would by no means be a difficult task to draw the parallel between the downward course of the drunkard and the thief, diving deeper and deeper in their potions and portions, ere the one becomes a drunkard and the other a cracksman But here the parallel ceases, the one finds himself in jail under sentence of death or in the penitentiary, where both should be, and the other in an inebriate asylum, petted and pitied for the sins of his fathers or the man from whom he obtained liquor Alas, for all such false philosophy and and wasted sympathy

Getting drunk should be considered a deliberate act in the face of common sense Yet there are advocates against punishment for crimes committed by persons when intoxicated, on the ground that such persons are in a state of "temporary insanity" The arguments they use are of a piece with those which would hold the distiller or seller of the liquor wholly responsible, instead of him who deliberately buys and drinks it, and which, if pursued logically, would hold the manufacturer or seller of fire-arms guilty of every case of murder or suicide committed by using them And granted the "temporary insanity," what should be the retribution to him who induced it—who *voluntarily* placed himself in the condition to debase his race, to commit arson or murder, to wreck a train of cars or to sink a ship?

Alas, drunkenness is the crime of crimes And the National and State governments which enact license laws which permit and assist in the sale of liquor, that aids and promotes drunkenness, or that people and community which permits or tolerates the establishment of saloons in their midst, are aiders and abettors of the crime

Let this numerous and representative body of medical men in whose hands are the issues of life and death, and who have so often in times past sounded the alarm of impending danger, rise to the importance of the danger by sounding the alarm against this Goliath of vice and crime Let the Medical Profession in its national capacity issue a new proclamation and, if necessary, put new sentinels upon the watch towers to warn the people of the rapid and perceptible inroads that alcoholic beverages are making upon the human race

Let the Medical Profession proclaim the fact that modern science and the latest investigation have sufficiently proven that alcohol destroys the *natural forces of the body*, that it *retards* and *prevents* the *development of the nervous system*, which effect is even extended to the *unborn infant*, that it perverts and deteriorates the red corpuscles of the blood and interferes with its natural flow, that it is not a preserver or conserver of *mental* or *physical* powers, that it does not and can not *per se*, form true natural tissue or good blood At the rate drunkenness is increasing in civilized communities, it is estimated by good authorities that in a little over one hundred (100) years the Caucasian race will degenerate to the level of the Mongolian, and become subject to all kinds of immoral practices In proof of this, I may cite the "result of the anthropometric examination of fifty (50) habitual prostitutes, who had been inmates of brothels for not less than two years, reported by Dr Praskovia N Tarnovskaia at the first Congress of Russian alienists at Moscow" (*Vratch* No 9, 1887, p 216) For the sake of comparison the Doctor examined in the same way fifty peasant women of the same age and as far as possible of the same intellectual development, etc

The result of this unique investigation may be summed up as follows

1 The prostitutes presented a shortening, amounting to half a centimetre, of the anterior, posterior and transverse diameter of the skull

2 As many as 84 per cent of the habitual prostitutes showed various signs of physical degeneration, such as irregularity in the shape of the skull, symmetry of the face, anomalies of the hard palate, teeth, ears, etc

3 In 82 per cent of the prostitutes the parents were habitual drunkards

Can any physician, can any thoughtful person, after reading this appalling statement of facts, close his eyes to the true *modus operandi* of alcoholic stimulants, or deny its *deteriorating* and *destructive influence* upon the *human system?*

Formerly the medical profession through lack of

experimental and practical knowledge of physiology and chemistry, but little understood the action of alcohol upon the human system, and therefore they *recklessly* and *indiscriminately* prescribed alcohol to their patients in season and out of season, which has resulted in inculcating much of the habit of inebriety among the people

Hence the medical profession should be *first* to voice the results of the modern investigations which point unmistakably to the destructive action of alcohol upon all the tissues of the body, and especially upon the nervous tissue And the sooner professional, personal and public effort is exercised in exposing its nakedness and its destructiveness, and making it odious and punishable, instead of apologizing for it and making it excusable, either in the seller or the drinker, the better for society and for the human race

A CASE OF PYO-SALPINX—RECOVERY WITHOUT OPERATION WITH REMARKS ON TAMPONNEMENT OF THE VAGINA IN PELVIC INFLAMMATIONS

Read before the Section on Obstetrics and Gynecology, at the Thirty eighth Annual Meeting of the American Medical Association held at Chicago, June, 1887

BY WILLIAM WARREN POTTER, M D ,
OF BUFFALO N Y

When the science of gynecology began to differentiate the pelvic diseases of woman, a vast field, before either untrodden or only slightly so, was thrown open in the domain of gynecological therapeutics, which is now being cultivated with an interest, assiduity and success, not second to that in any department of medicine Time was, and that not so very long ago, when it was sufficient to tell a woman she had "ulceration," or "prolapsus," or "inflammation," and it was understood that these conditions all belonged to the womb itself, for the other pelvic organs had hardly been explored in a pathological sense Now it is essential, not only to define the character and degree of a uterine displacement, to diagnosticate between ulceration, erosion, and laceration of the cervix, and to untangle the various forms of inflammatory action to which the womb is liable, but we must understand and explain the multifarious sympathies and reflexes which these several conditions engender or lead up to Nay more the ovaries, tubes, ligaments, bladder, rectum, cellular tissue, and peritoneum, must all be carefully and patiently searched for any absolute or latent changes in structure, shape, or function All this, and even much more not necessary here to enumerate, it is absolutely requisite that the gynecologist should know and utilize in his daily investigation of cases, even patients are satisfied with nothing less, since they, themselves, have in a measure kept pace with the progress of events, obtaining, in one way and another, a fairly intelligent understanding of their own cases

One of the important consequences of the more accurate differentiation and classification of pelvic disease, has been to invite surgical aid and interference in regions which were previously considered unsafe for the knife, and for maladies which had before been regarded as incurable The road to fame is so direct, and its way so broad and inviting, through the open gateway of a brilliant and hazardous surgical operation, it is neither strange nor surprising that many men, ambitious for a distinction which can be so suddenly attained, have eagerly embraced opportunities to lay open the abdomen in search of an offending ovary, or tube, or a mischievous morbid growth of some kind, justifying the procedure upon a successful result, or, if not this, then upon the reported success of somebody else in an apparently parallel case

The value of the work of Battey, Tait, Hegar, and others, and the benefits which their researches and teachings have accomplished cannot well be computed, nor is it my purpose to disparage it or speak *slightingly of them,—I would not if I could,* I could not if I would When their work is properly understood, its application to diseases of the uterine appendages justly made, and the balance sheet fairly struck, it will be found that there has been great and inestimable gain But will it not be just as certainly discovered that their teachings have often been misunderstood, their deductions misconstrued, their cautions unheeded, and their results misinterpreted, and further that, as a consequence, much of the surgery of the abdomen in this field has been done either indifferently well, or unnecessarily?

Following upon a few established successes there has been, of late years, such a stampede of gynecologists towards the Mecca of laparotomy, that there is some danger of neglect in the comparatively minor fields *I have,* myself, known a most capable and distinguished teacher and worker, skilled in all the various details of gynecology, become so captivated with abdominal surgery as to fairly dread the care of any other class of cases, and to become impatient and restless over the lesser maladies in the department of diseases of women for which he was consulted This eager chase for fame in the direction named, and the interest which naturally attaches to its recital, has so whetted the appetite of the profession for such literature, that it requires some courage to seek the ear of an assemblage like this, with anything less than a formidable array of cases, duly tabulated, classified and analyzed, showing a year or two's work in this seductive and fascinating field, and these statistics, when amply fortified with pockets full of ovaries and jars filled with tubes,—trophies of the bloody conquests—bear testimony in no uncertain manner to the fierce battles and renowned campaigns which the courageous author has waged against the reproductive organs of woman, all done under the most approved and painstaking antiseptic precautions

But may it not be possible—barely possible—that some of these operations could have been avoided and the organs saved, by the adoption of a more conservative plan? Bear with me while I relate a

case, which will serve as a partial answer to this question from my standpoint, and which I promise shall be brief, even if it shall possess no other merit

About a year ago a patient, recommended by another physician, came from a distance to reside near me for professional care The previous history of her illness may be summarized about as follows Eight months before she presumably aborted, though neither she nor her attendants—physician or nurse—were ever quite sure that they saw a fœtus, the supposition being that the embryo escaped, unobserved, with the membranes intact This happened in her first pregnancy, about two years after marriage, from which time forward, November, 1885, she was never in good health The winter was passed in a state of invalidism, though she was not altogether compelled to keep in bed Early in March she had a hæmorrhage, not very severe, but it continued rather passively during that month and the most of April, associated with pain and a general physical enfeeblement The flow finally abated or came and went alternately, but the pain increased, becoming at intervals quite severe, the abdomen began to enlarge, particularly on its left side, growing tender as well, so much so, indeed, as to render even the lightest clothing oppressive During May and June there was apparently some general physical improvement, but never a long cessation of pain, and menstruation was irregular and otherwise unnatural So much for its history before I saw the case

Upon my first examination, early in July, there was great tenderness of the intra-pelvic organs and tissues, the fundus uteri was swayed toward the left, and there was fixation though not much enlargement of the womb There was a large banana shaped bunch at the left of the uterus which could be outlined externally, though the degree of palpitation necessary to an accurate diagnosis was so painful that I deferred any opinion until further observation The cellular tissue was hard and tense, indicating unabsorbed exudate around and adjacent to the left broad ligament, and a week later I felt distinct nodular masses along the vaginal roof As time went on the density of the cellular tissue diminished, the mobility of the uterus correspondingly increased, and the tenderness likewise lessened, to an extent which soon permitted sufficient bi manual manipulation to outline a distinct enlargement of the left tube, thus explaining the banana like tumor before observed This finally grew softer and pus was discharged through the uterus late in August, during my temporary absence from home On my return I found considerable diminution in the size of the tube, and much relief from pain, together with a general improvement in health, manifested particularly in a greater ability to walk, which had before been impossible to any extent

This improvement was continuous until October, when the tube again grew tender and swollen, but another discharge of pus, also *per vias naturales*, though less in quantity than the first time, soon brought relief again From this time onward the gain was regular without interruption, the shrinkage going steadily on and the strength improving, until I dismissed her about April 1st, of the present year, practically cured I have been thus specific, that there might be a clear understanding as to the grounds on which the diagnosis was based

Now for the treatment I commenced, *in limine*, a systematic and regular tamponnement of the vagina, packing it neatly and snugly, but not forcibly nor oppressively, twice a week, employing for a day between each packing copious lavements of hot water The hot vaginal douche was also used thoroughly each morning of the treatment, just prior thereto, after which the vagina was insufflated with iodoform, bismuth, mineral earth or other powder, and then the small pledgets of cotton, wool, or jute, were introduced in sufficient numbers to make gentle, firm, and even pressure, as well as afford comfortable support The tamponnement was done either in the Sims' or knee chest posture—generally the latter, as it proved the most comfortable to the patient and, likewise, permitted the utmost thoroughness in the work Such relief did this plan of treatment afford the patient, that she readily lent an earnest and hearty co operation in carrying it on, and, moreover, whenever it was interrupted for a few days, as occasionally happened from one cause and another she observed such a marked change in her symptoms and feelings, that I was induced to instruct another physician, as well as her nurse in the method, so that the work could be carried on whenever I was unable to attend to it myself

Finally, appropriate constitutional treatment, principally iron and arsenic in one form and another, was associated with the local measures described, and this was all There was, to be sure, much of detail not necessary to elaborate here, but these were the essential factors of the entire management, and they were continuously employed during a period of nine months

Other cases of a somewhat similar nature, and likewise similarly treated, have fallen under my observation, but this one is sufficiently typical of its class to illustrate my meaning and emphasize my purpose in seeking the ear of the Section at this time Of course I shall have missed my object entirely, if I have failed to impress two points with sufficient impact to challenge attention, thought, and criticism, viz

1 That many cases of disease of the uterine appendages may be arrested in their progress and diverted to successful issue without operation, by appropriate treatment resorted to in their earlier stages

2 That the early employment of regular, prolonged, and systematic vaginal tamponnement affords one of the safest, surest, and simplest ways of preventing the ravages, in whole or in part, of the maladies in question, and of averting that mutilation of the sexuality of woman consequent upon excision

VAGINAL TAMPONNEMENT

This occasion presents to me the opportunity of offering some remarks upon the employment of vaginal tamponnement in the treatment of pelvic disease in general, which I gladly avail myself of, since

it is a subject which is again creeping into medical literature, through society discussions and papers In a paper which I read before the Medical Society of the State of New York some years ago, this subject was discussed in considerable detail, with special reference, however, to its employment in the management of uterine and ovarian displacements Now, with the added experience of years and cases, I desire to reaffirm and supplement my former statements, extending the principles to the treatment of inflammatory conditions of the intra pelvic viscera and tissues of whatsoever nature or cause, whenever they can be made applicable At that time my experience was limited to the tampon formed of cotton alone, or nearly so, but now I find wool and jute even more serviceable in many cases, and in this experience I am happily in accord with many other observers In the paper referred to I spoke emphatically against the use of the absorbent cottons, finding them too inelastic when wetted, either by the medicated fluids in which they were dipped, or by the natural or unnatural juices and fluids of the body which they absorbed after introduction In either case they become too sodden and boggy to avail much either for support or elastic pressure, and these are the particular indications of treatment to be fulfilled

To obtain the full benefits of this treatment in pelvic inflammations, as well as displacements of the viscera, or for other conditions in which it may be employed, it is of the first importance that the packing shall be well done It must be so placed that it will afford ample support, give secure rest to the parts, make firm pressure, and not become dislodged or sag during its wearing, while, at the same time, it must not produce discomfort, interfere with the functions of the pelvic organs, nor cause irritation in the least degree To this end the tampon must be multiple, *i e*, it must consist of several small pledgets, introduced one after another until constructed of sufficient size, and not made a single large wad or mass, which fits nobody This is important, since much of failure or discredit to the method, comes from faulty construction of the tampon, or its ineffectual placing, or both These pledgets should be prepared beforehand, to each of which should be attached a thread (Coates' No 8), upon which traction can be made by the patient in their removal, singly or in groups, according to the convenience or necessities of the case The threads can then be united in a single knot and left hanging from the vulvar orifice, or tucker inside the vagina if preferred The principal point is, that every nook and cranny of the vaginal cavity shall be occupied, while due caution shall also be observed against overdistention, and this, I affirm, can only be accomplished by means of the multiple tampon It is well to have the vagina first thoroughly washed out with hot water, then dried, and finally insufflated with some appropriate powder, before the tamponnement is begun This serves the double purpose of contributing to the retention of the tampon firmly in its place, and of rendering it antiseptic

Formerly I was in the habit of saturating the first or upper portion of the tampon—two or three pledgets—in a glycerate of iodoform, tannin, or other material, but of late, acting upon the suggestion of Dr Engelmann, of St Louis, I employ dry powder in the main, and obtain much satisfaction in the use of subnitrate of bismuth, which appears to have the widest range of adaptability of any remedy with which I am now familiar,—iodoform, and mineral earth standing next on the list in useful importance The tannate of bismuth serves a good purpose, when an astringent is needed

When Dr Engelmann first advised the use of bismuth, for it was he who brought it to my notice in connection with his plan known as the "dry treatment," I confess that, being not a little skeptical on the subject, I used it somewhat half-heartedly at first and, therefore, did not obtain satisfactory results, probably in part because I did not employ it with that precision and thoroughness which I ought, but certainly in great part because I did not fully comprehend its capabilities Now, after a considerable experience with the dry method in general, and with bismuth in particular, I am prepared to endorse, as far as my experience goes, all that he claims for them. While it is probable there are cases, and I have seen such myself, that thrive best under the moist treatment, yet I consider his plan a decided step in advance, a considerable reinforcement to our resources, and, if his directions are adhered to in carrying it out, I believe a greater measure of success in the management of pelvic inflammations will assuredly follow

One word as to the position of the patient during tamponnement, since this becomes a question of considerable importance if we would attain the highest degree of success Taking it all in all, I believe the knee chest posture approaches nearer the ideal for this work than any other The semi prone or Sims' position becomes some cases when, for any reason, the other is inadmissable The dorsal decubitus is almost worse than useless for the business in question, since, with the woman lying on her back, it were impossible to crowd the tampon up behind the uterus, or any other tender organ, with sufficient firmness to make it either useful or retentive In the genu-pectoral posture, however, it is comparatively an easy matter to restore the pelvic organs, in the majority of cases to their proper level, for in it we obtain a reversal of normal gravitation—an aid of no mean import, when the structures are so very tender as they are usually found to be In this position the impacted organs, with their tissues more or less engorged, become readily unshipped from their habitats, and measureably restored to their proper places, the entire field is brought within easy view, and everything conspires to simplify the process of constructing the tampon in a thoroughly mechanical manner

Since 1877, when, following the teachings of Dr. Henry F Campbell, I first began the systematic use of the knee chest posture in the reduction of pelvic visceral displacements, and of the multiple tampon a year later in conjunction therewith (at the suggestion of Dr Bozeman), I have employed them in

many hundred cases, and the statements here made are the outgrowth of, to say the least, not a limited observation in the direction named As a result of this experience I have reached the following conclusions

1 In retro deviations of the uterus the reposition of the organ should be made in the genu pectoral posture, without the aid of any other repositor than the finger, it should then be shored up and held in place by the multiple tampon This treatment should always precede the employment of the pessary (when one is required) for a longer or shorter period, according to the peculiarities of each particular case

2 The foregoing applies with equally cogent force to inflammations and prolapses of the ovaries, whenever these principles can be adjusted to such cases

3 In abrasions, erosions, and ulcerations of the os, in the hyperplastic womb, in lacerations of the cervix, in subinvolution, in cystocele, in rectocele, and in all conditions of disturbed or impaired nutrition of the pelvic organs, it affords a most efficient form of either preparatory or curative treatment, tending to give the organs rest, restore their tone, deplete engorgement, remove blood stasis, improve locomotive power, and arrest retrograde tendences in general

4 In pelvic inflammations whether of cellular, peritoneal, tubal, or other origin or involvement, it will often change their current or arrest their progress, prevent suppuration or abridge its ravages, and thus frequently guide to a successful issue, without the necessity of a final appeal to a formidable and perhaps dangerous operation

Dr J H Etheridge, of Chicago, in his published remarks on this subject, has very succinctly and aptly said that, "The inflammations of the uterus we are usually called upon to treat are not active, but chronic, and if we hold the uterus up so that it can drain itself properly through the veins, the nutritive changes which take place will be facilitated to the greatest extent" And again "When the uterus is enlarged it becomes heavy, sinks, and presses the veins which carry the blood out of the uterus, and we have strangulation By raising the uterus up, the blood flows freely and the nutritive changes always tend to health" These are the wise words of an accurate observer, and deserve repetition as expressing, better than I could, one of the important ways in which benefit is obtained through this method of treatment

Finally, I may remark that, though it does not fall within the scope of this paper to discuss this interesting subject exhaustively, I have sought nevertheless, to touch upon some of its prominent features, hinting here and there at points of importance in its application, and glancing at some of the salients of its detail, trusting to the discussion which I hope may be elicited, to elaborate and embellish the text better than I could, or, perchance, to open up new or little-trodden paths for exploration

284 Franklin Street

DISCUSSION

DR J H ETHERIDGE, of Chicago Very little remains to be said, it seems to me, in addition to what the Doctor has given us, and I think he is to be congratulated upon the completeness of his paper, as he covers the ground very thoroughly I will mention a few points in addition, which may be of interest He says that he tampons the vagina with successive pledgets of cotton or wool and attaches threads by which they are withdrawn In rather an extensive experience in the use of this tampon for these troubles I have found a small long strip of antiseptic wool, about as wide as my three fingers, can be very readily carried up with the dressing forceps until the whole vagina is thoroughly filled The tampon will remain in place in some cases many days without any inconvenience as to the odor or irritability of the organs that it supports I have made a universal practice to leave it, if there is no unusual odor or discharge from the vagina, I leave it in four, five and six days and have left it in as long as ten days I am now treating a patient for prolapse of the ovary, who was almost a total wreck, when I began the treatment She had gone to bed to stay there permanently, two or three times in the middle of the month she got up and went around a little, but she was not half a woman, she thought This method of treatment was instituted, the vagina packed full with the wool and the very next day the woman went out shopping and she has been out every day since At first I used to remove the tampon and let her menstruate while in a recumbent position, but one day she got the start of me, the day before I reached her the menses came on and she still wore the tampon She experienced no inconvenience and there was no disagreeable odor about it, so she wore the tampon for a period of four or five days, during the flow and at the end of that time I removed it During her menstruation she went out, ran up and down stairs and all around and since then she has insisted on wearing the tampon through her menstruation, and I have been afraid to take it away from her I cannot reach the ovary now I keep on using the tampon but I have adopted this plan, twelve hours before I saw her the last time, I had her remove the tampon and do as she was inclined, go up and down stairs and do what ever she wanted to with perfect freedom By and by when I find I can let her go a week or longer I shall place the tampon just a week before menstruation and after awhile shall leave it out altogether If called upon to give an opinion as to the greatest field of usefulness of this tampon I should say movable ovarian prolapse

DR C R REED, of Middleport, Ohio I listened to the paper of Dr Potter with a great deal of interest, but I was reminded, after the conclusion of the paper and the remarks of the gentleman who has just taken his seat, that we are rapidly going back to the method of Dr Hodge of Philadelphia Twenty years ago in his work on "Diseases of Females," he recommended the use of the lever pessary in almost all diseases of the pelvic organs He said it would cure almost any of the forms of disease from which women suffered at that time, displacements of the uterus and ovaries, and he claimed and reiterated it with just as

much apparent authority as we now hear in favor of the tamponnement with jute or oakum or wool, that the proper form of lever pessary properly adjusted would overcome all these troubles if persevered in He condemned the use of caustics and other applications to the cavity of the uterus or to the cervix and os, and forcibly impressed it on the readers of his book I have no doubt that this treatment when successfully carried out will accomplish what the gentlemen claim for it, but, as I said, it reminds me of Dr Hodge's lever pessary There was one advantage of the pessary over the treatment recommended by the paper, it left the vagina free and unobstructed A pessary of proper size and shape had to be adopted and if one would not do the shape should be changed until it did answer the purpose It was the same claim made by Dr Potter, holding the organ up in its proper place

Dr Wagner, of Kansas City In order to get even with the gentleman, who has cured one case of pyosalpinx without operation, I had one case that I diagnosed as pyosalpinx that died for the want of an operation We insisted upon it but were not allowed to make an operation The pus was evacuated into the peritoneal cavity, and the woman died in a short time I would like to ask the gentleman who gave such immediate relief for prolapsed ovary if he expects that to be the end of the case?

Dr Etheridge Time alone will tell

Dr Bingham I wish to endorse the paper which we have just heard read, in every respect, as, in spite of the fact of Tait's results and the results of other men, my experience has taught me that the opening of the abdominal cavity is not the mild, simple, easy operation that some would lead us to believe I indorse the gentleman's views that before an operation, involving such risk as is inevitable in almost every case of that kind, that every means, short of abdominal section, should be used first, and then having failed we have that remedy as a *dernier ressort* I believe Dr Potter will indorse that view, and that when nothing else will do he will remove the ovaries But it is by no means a harmless operation The removal of a Fallopian tube for pyosalpinx is often more difficult than to remove an ovarian tumor Some doubt has been thrown on the correctness of the diagnosis in the case of pyosalpinx, in which tamponnement and appropriate treatment produced what we may well call a cure, and that without any particular risk to the patient, or the doctor either I believe that the Doctor is correct in his diagnosis and I know he is correct in his management of the case, as given to us Within the last year I have had under my care almost the same kind of case with a similar history, in which there has been repeated accumulations of pus, that could not have been any place else except in the Fallopian tube, and, had I had the skill that some have, I have no doubt I could have passed a sound into the Fallopian tube

Dr A S von Mansfelde, of Ashland, Nebraska I am surprised that the gentlemen, who spoke, have left untouched the main part of the paper The author throws out the proposition that it is in many cases necessary to operate in suppurative disease of the Fallopian tubes, then he tells us he had a case of pyosalpinx that he did not operate on, but cured Did he have a case of pyosalpinx? It reminds me of a case, in Chicago, not many years ago One of the professors of a leading college promised us a case of tumor of the breast upon which he would operate at the next session In the meantime he applied a poultice to the breast, though it appears he did not know what he did it for, and when the patient was brought into the lecture room and anæsthetized he found no tumor Now is it not possible that the gentleman had a case of pyosalpinx without the pus? It is certainly true that the greater number of cases of pyosalpinx owe their existence to gonorrhoea, that is a fact that nobody can deny When you have a case of pyosalpinx caused by that disease all the tamponnement in the world could not cure it There are only three terminations resolution, caseation or *coagulation necrosis, and rupture of the sac* The experience of the gynecologist is that the sac will rupture in the majority of cases I come from a part of the country where we are always in a hurry, we have not time to wait long, and it is not considered good practice or good surgery to let a case of pyosalpinx go many days and wait for nature to take its course, we open the abdomen and remove the Fallopian tube, and I think there are gynecologists in this room who will say amen to that Why we should preach a sermon of such magnitude upon a hypothetical case I cannot understand

Dr Green, of Indiana I simply rise to deprecate the sentiment of the gentleman from Nebraska, that physicians of the West are always in a hurry It seems to me that in the treatment of women, particularly in salpingitis of any kind, that to resort to the knife as soon as the disease is diagnosed is criminal There is no doubt in my mind that many cases of salpingitis may be cured by local treatment, neither is it doubtful that many must be operated upon, but that any physician, because he has a case of that kind and lives in the "Great West" should rush to the operation, is criminal

Dr W W Potter, in closing the discussion, said It is not necessary to take up much of the time of the Section, I want to note one or two points The question has been raised about the multiple tampon, Dr Etheridge find his manipulative skill so great that the single tampon answers the purpose I think it is a matter of individual tact very largely, I presume he may do quite as well with the single tampon as I and others do with the multiple tampon, but in the main I believe the multiple tampon has the widest range that is possible The point I want to make is that the vagina shall be neatly and perfectly packed without any undue distension or any disturbance of function, or irritation With reference to the question of retaining the tampon during menstruation, of course I could not cover every detail in a short paper, but it is very important I have seen cases over and over again, in which the woman would have excruciating agony during menstruation, and I have seen the pain relieved by forcing the ovary gently into its accustomed place, and holding it there during menstruation with the multiple tampon

With reference to the question of diagnosis, which the gentleman from Nebraska has raised, I left that to the judgment of the Section on a tolerably full report of the case, namely, a gradual pelvic inflammation which in the the first instance involved the cellular tissue and gradually crept into the tube, with slow exudation, being absorbed somehow, by manipulation this enlarged tube could be mapped out Without wishing to raise a laugh on this question, I submit that it would be well not to be in such hot haste in the matter as seems to prevail in Nebraska It is undoubtedly true that many cases of pyosalpinx are of gonorrhœal origin, and it is equally true that many cases come from other causes Dr Wagner, of Kansas City, has fairly presented the views I intended should be drawn from this paper

---

RETROFLEXED SPLINTS FOR FRACTURES OF THE FOREARM

Read in the Section on Surgery at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY W D KEARNS, A M , M D ,
OF PITTSBURGH PA

Novelty, although attractive, ever engenders doubt, and oftentimes hasty rejection, and every innovation challenges closest scrutiny When, however, practicable, safe and intelligent, as the exponent of full and sound principles and practice, it will, ultimately, be earnestly embraced and adopted Especially may this be said of the phenomenal advancement in the record of medical science of the present day Throughout all the "fearful and wonderful" mechanism of our creation, through all its ample endowments by Divine wisdom and infinite power, in variety, scope, application and execution, that member of our body, the hand, is preeminent And yet no member of the human body is quite so obnoxious to violent injuries as the hand and forearm, and for obvious reasons No bone of the human skeleton (except, perhaps, the clavicle), is so frequently the seat of fracture as the radius, and no fracture has, perhaps, received greater practical study than that of the lower end of the radius, known as "Colles' fracture "

To a hasty study, and to the ready application of the principles involved in the restoration of the skill of the hand and forearm, when maimed by fracture of the radius at the lower extremity, or, indeed, fractures of both bones of the forearm at any and all points, your attention is earnestly invited As the rehearsal of the descriptive relative anatomy or of the pathology consequent to fracture of the forearm would be an unnecessary use of your time and patience, beyond certain essential parts and conditions which can be referred to as we proceed in our recital, I will enter at once on the discussion of the subject of this paper retroflexed splints in the treatment of "Colles' fracture," a term adopted as significant of the point at issue, also, as has been suggested, "the extension of the hand on the forearm " "Value of Ingenious Splints" is the heading of a short extract from a lecture by Mr Hutchinson, of London, in an issue of the *Medical and Surgical Reporter*, in which this distinguished surgeon says "that, as a commentary on the futility of inventing complicated splints and apparatus for fixing limbs, none of which ever meet general approval, he might refer to an ingenious instrument devised by Dr Gordon, of Belfast, after long continued anatomical study of Colles' fracture This, which was intended for general use among surgeons, is figured, says Mr Hutchinson, in a text book by a leading surgeon, *upside down*, and assuming from this, that even the author of the work is practically unacquainted with the splint, although he writes about it, what chance is there of its being universally adopted?" He goes on to say that not only Colles', but all fractures, are most successfully treated by extension, which can readily be applied through the agency of a simple straight splint, and, he continues, very thick pads should be fitted to the splints Now, this last consideration—this necessary and judicious stricture, evolves the great practical point in our present discussion, and introduces the great results in practice through the successful application of the principles advanced in the heading of this paper, and *a priori* concedes this acknowledged inefficiency of straight splints in seeking the aid of thick pads

The sad results, so often witnessed, in the marked "silver fork" deformity, the great abridgement and relative loss in the free movements and skill of the hand, for many weeks, and in elderly patients, perhaps for life, are a source of great dissatisfaction and perplexity We most naturally seek such measures as may aim at their prevention Whilst, at times, the fracture may be transverse, yet it is the common form, the oblique, and even more or less longitudinal, that present obstinate and persistent difficulties, the greater resistance to retention, and are the more exacting of the retaining splints

Complete reduction of the fracture is absolutely required, whatever form of splint may be applied, but the disastrous impairment of the functions of flexion, extension, pronation and supination, the anchylosis due to the inflammatory processes along the sheaths of the muscular tendons, ligaments and fasciæ, these mischievous structures must, if possible, be averted, and this insufficiency of the straight splint, however deeply padded, to secure the necessary angles of flexion of the wrist, and the metacarpo phalangeal articulations, suggested the congruity of the flexed splint—a splint less complicated than a thickly padded straight splint, inasmuch as a comfortable condition, and proper relaxation of all the tendons and fasciæ of the forearm and hand, are at once permanently secured

Whether, then, the fracture of the radius be transverse, oblique, more or less longitudinal, or more or less comminuted, the conditions governing the form of the retaining splints are, after complete reduction, alike exacting, and may be, it is maintained, best subserved by "retroflexed splints," which seem greatly effective in preventing the formidable impairment of the functions of flexion, extension, pronation and supination, such attained relaxation obviating the inflammatory adventitious processes in the sheaths of the muscular tendons, ligaments and fasciæ, whilst the bony structure is progressing, through the analo-

gous process of provisional callus, to ossification

The essential principles maintained in the treatment, not only of Colles' fracture, but in that of all fractures of the radius and ulna, may be generalized as consisting, after careful, complete reduction, in the maintained complete relaxation of the muscular tendons of the arm, forearm and hand, of the fascia and ligaments of both superficial and deep flexors of the anterior brachial region, of the pronators, and of the superficial and deep extensors of the radial region, to their tendinous insertions, even of the short and seemingly unimportant muscles and fasciæ of the palmar surface of the thumb, the early, free use of the thumb adding greatly to the early use of the hand The continued maintenance of this relaxation is of paramount importance in connection with the immobilizing of the wrist, the proximal point These essentials are the great recommendations of the "retroflexed splint "

Gray's "Anatomy" furnishes a plain, practical illustration of the muscles engaged in the displacement of the fragments in Colles' fracture, disclosing the acting causes of the biceps, the pronators, and supinator longus, where it is seen the upper fragment is under control of the biceps, lifting the upper fragment further from the ulna, the pronator radii teres drawing the upper fragment inward, the pronator quadratus drawing the lower fragment inward, near to the ulna, the supinator longus, contracting, lifts up the styloid process of the radius, pressing down upon the ulna the lower fragment How readily is the displacing power of these muscles intercepted through the ordinary mode of the flexion of the fore arm on the arm, a simple bend at the elbow, a like bend at the wrist will yield like good

When both bones of the forearm are broken—as when but one—the use of thin, narrow, interosseous pads will exercise a controlling force upon the displacing influences of the pronator quadratus and the supinator longus The continued, strained abduction of the hand on Nélaton's "pistol shaped" splint, if abduction is sufficiently prolonged to produce any tangible effect, presents and exercises an unnatural and uncomfortable condition

Again, splints, to be effective, should immobilize the proximal point, hence, short splints, or even a short palmar splint, and a long, straight dorsal splint, are alike inadequate, for, says Miller (Principles of Surgery), "in fractures of the radius, for instance, unless the wrist be completely commanded, pronation, inevitably causing displacement, ill adapted callus and a weak as well as unseemly limb, will certainly occur " A short splint, extending a little above and a little below the fracture only, says Dr Potts, is not only an absurdity, but a mischievous absurdity The necessity of the greater width of the splint than the encased limb, to obviate consequent depression and displacement of the fragments by the retaining bandage, is a familiar safeguard

The dressing of the fracture is very quickly done, and no removal of the splints is required for the satisfactory examination of the arm Both splints being thickly inlaid with absorbent cotton, having three strips of adhesive plaster at hand, an inch or two in breadth, placing the inside splint along the arm, grasping the hand of the fractured arm with the surgeon's right hand, sufficient traction is made, whilst the left hand retains the inner splint, and feels the fragments in proper apposition—the outer splint is applied, and clasping both splints firmly, a strip of adhesive plaster encircles the splints at the wrist firmly, another at their upper extremity, and another around the hand part of the splints In case of fracture of both bones, an interosseous pad should be invariably applied and can be placed and held *in situ* by the same original grasp These adhesive strips hold firmly the splints, when the retaining bandage may be leisurely applied

It may be noticed that the hand end of the splints admits of slight drooping of the hand, the simple curve of uncontrolled muscular action It will be observed, also, that the angle of retroflexion of the dorsal splint is studiously sharp at the wrist, an angle of about 122°, applying the pressure from the splints only to and upon the extremities of the radius and ulna, carefully avoiding any and all pressure upon the carpal bones This angle should be of degree sufficient to secure complete relaxation of all the posterior muscular tendons above mentioned by the backward bend of the hand, whilst the partial closing of the hand secures the necessary relaxation of the anterior tendons and fasciæ The palmar splint continues on over the muscular prominence of the three flexors of the palmar surface of the thumb, preserving their full unconstraint, whence it dips backward, spreading over the palmar surface of the partially closed hand

While we have invariably, for many years, applied a bandage to every fractured limb previous to the application of the splint, yet would this careful custom, from recent teachings, seem more honored in the breach than in the observance, for, says Dr John H Packard, in the fourth volume of Ashhurst's "International Encyclopædia of Surgery " "In former times a custom of applying what was known as an 'immediate bandage' to a fractured limb, in order, as was supposed, to prevent muscular contraction This custom has now been generally abandoned, although it is still followed by some practitioners, it can never do any good, and may do much harm " Yet, with profound respect to this authoritative source and consideration, an "immediate bandage," loosely and intelligently applied, may do some good in controlling muscular action, and preserving the contour and integrity of the relative anatomical cast and condition of all within its envelopement—a tegumentary supplement In fractures of both bones it were best omitted

The retroflexed splints, then, give a ready, comfortable and effective maintenance of all appreciable, required muscular relaxation of the extensors and flexors, traversing in their tendinous sheaths beneath the anterior and posterior annular ligaments to their ultimate insertion along the phalanges, and relaxation of the muscles and fasciæ of the hand and thumb, and, lastly, may they justly claim an eminent preferment in securing the early, free, and full use of the hand

A CASE OF HYSTERECTOMY

With Practical Remarks on Laparotomy

Read before Indiana State Medical Society, May 11, 1887

BY JOSEPH EASTMAN, M D,

PROFESSOR OF GYNECOLOGY, INDIANAPOLIS, IND

Mrs W, married, aged 35, mother of two children, the youngest 5 years old, consulted me on December 28, 1886, concerning a tumor which she had first noticed about four years previously During the two or three months preceding her visit to my office, the tumor had given her much annoyance, becoming painful and tender, especially at her menstrual periods These complaints were accompanied by more or less hectic symptoms, the temperature running as high as 101°–102° F, with deranged digestion

By the usual methods of examination in such cases I had no difficulty in excluding all but two conditions, namely, multilocular ovarian cyst with very short pedicle, or myoma, soft fibroid of the uterus The uterine cavity measured two inches I advised abdominal section and removal of the tumor, of whatever kind it should prove to be The patient could not consent to be "cut open" during life, but was anxious to have it done *post mortem* At her next period, however, her suffering and debility became so great that she submitted "for her children and husband's sake to make the leap for life"

She was admitted to my private Hospital for Women on February 1, and at once put upon preparatory treatment to reduce temperature, control hectic symptoms, etc In spite of treatment during three days the temperature ranged 100°–102°F The secretions and excretions being good as could be expected, I opened the abdomen on Februray 3, by an incision two inches in length, and plunged a trocar into the tumor No fluid escaped, but a red blush spread over the surface, characterizing a tapped fibroid The incision was enlarged, extending to the umbilicus, the tumor turned forward and out of the abdomen, the broad ligaments were clamped and ligated with cobbler's stitches, then separated by the cautery The pedicle was clamped with Eastman's[1] large temporary clamp

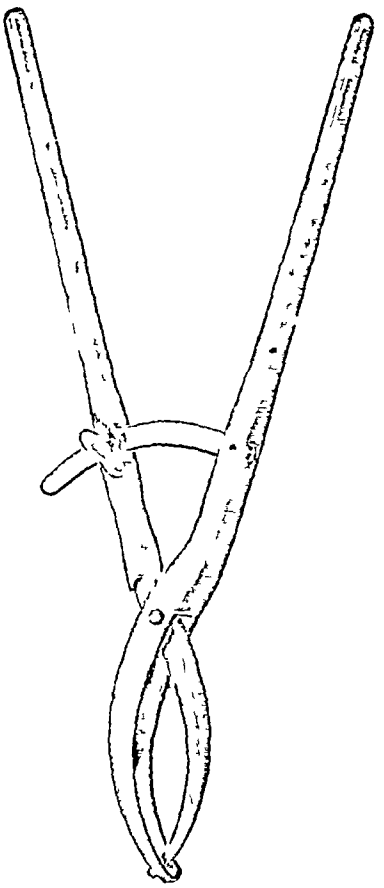
A strong elastic ligature was passed around the pedicle as low as the vaginal attachment, and then it was severed between the clamp and the ligature A cone shaped piece of tissue was cut out of the stump, the apex pointing toward the internal os, the base directed upwards and outwards towards the serous membrane A cautery iron at blue heat was three times passed through the cervical canal from above downwards, for the purpose of destroying mucous membrane and to afford drainage from the interior of the stump A dressing forceps was passed through after the cautery, by the aid of which a rubber tube as large as my little finger, was dragged up to within half an inch of the free peritoneal margin I expected this tube by its expansion to resist shrinkage of the stump The elastic ligature was then removed and over the tube the stump was stitched with number 14 iron dyed silk, the stitches being placed in cobbler's style, three-fourths of an inch from the free peritoneal margin

After ligating the arteries these flaps were brought together by Lembert's suture, it requiring twelve of them The peritoneal cavity having been cleansed, a glass drainage tube was introduced through the opening, into the cul de-sac of Douglass, and then the abdominal wound closed with silk sutures The tumor weighed six pounds

There was little shock, the temperature never reaching above 101° F, except for about one hour, during the action of the first cathartic when it was 102°

REMARKS ON LAPAROTOMY

It will be seen from this report that I used Schroeder's intra peritoneal method of treating the pedicle, with my addition of inserting the elastic tube through the cervix, to expand and resist contraction of the tissues at the seat of the ligatures I should use the



[1] Eastman's clamp as here shown is made in two sizes by Shepard & Dudley, of New York, and has the following advantages

1 It is long enough to enable the assistant holding it to be entirely out of the operator's way

2 It is so strong that there need be no fear of its breaking, whatever force be exerted, purposely, or otherwise

3 It has no complicated machinery to get out of order at a critical moment "The simplicity of an instrument is a measure of its success"

4 No matter how large or how small the object grasped, the pressure is the same at either extremity of the clamping jaws, the latter being so constructed that they will not allow any substance to slip, neither will they cut

5 It will crush a substance as small as a shoe string, or the base of a tumor six inches in diameter This is an advantage where the pedicle is short and more room needed for the ligature

6 It instantly arrests all communication between patient and tumor, so that in striking the peritoneal surface of the tumor can not chill the patient and cold blood returning from the veins is an important source of shock

7 It instantly arrests all escape of arterial blood, which is sometimes great when we have broken up the partition walls of a cyst to reduce its size, and

8 As in this case, where the pedicle includes the uterus at the internal os, it clamps it so as to reduce the mass more than one half

same method again, giving free drainage, not only because the result was good in this case, but because I believe where it can be done it is the ideal method Keith and Bantock admit that this is the true method Yet at the same they get the best per cent by fastening the pedicle outside Schroeder, I believe, at the time of his death had some unpublished statistics, showing a lesser mortality by his intra peritoneal mode Formerly the subserous variety of fibroids, with pedicle, were the only ones admitting of radical cure by surgical means Now we make an abdominal incision and remove the *subserous* variety by enucleation or hysterectomy, in cases where emergency demands it

I admitted before this operation that I did not know whether I had to deal with a cyst, or a myoma Tait says the differential diagnosis is extremely difficult In a conversation with Dr John Homans at his private hospital in Boston, on the second day of this month, (May), he said "It can not be done" I fully agree with his opinion as expressed, especially when, as in my case the uterus could be well defined by rectal and vaginal exploration, the soft myoma enabling the sound to move the uterus without any perceptible movements of the abdominal tumor

This case teaches this lesson That exploratory incision is warranted when the diagnosis can not be clearly made out, (and our most experienced abdominal surgeons admit we can never do it with certainty) provided he who does it is fully prepared to do *any* operation known to the surgery of the abdomen, and is able to care for his patient afterwards according to the most approved methods to detail and provide the same surroundings for his patients as do those operators whose increased personal experience and success has given them such a low mortality that they unhesitatingly publish their death roll along with their successful cases

Dr Thomas, after an experience yielded by seven or eight hundred cases, approximately, extending over a period of twenty years, feels that he can say with truth that he has never once regretted opening the abdomen, and that he has in a dozen cases deeply regretted not having done so He thinks it certain that in the future exploratory abdominal incision will become the rule in all cases of the following conditions which do not yield to medical means, and concerning which the etiology is in great doubt 1 Wounds and injuries of the abdominal viscera, 2 Intestinal obstructions, 3 The presence of stone in the bladder or kidneys, 4 The accumulation of blood, pus, or serous fluid from any source, 5 The existence of a neoplasm in any part of the abdomen, 6 The occurrence of serious organic changes in certain of the viscera of the abdomen, such as the kidneys,the spleen, the uterus, the Fallopian tubes, or ovaries, 7 Ectopic gestation

This noted abdominal surgeon has completely cured a humber of aggravated cases of ascites, after tapping had been repeatedly resorted to, and all hope of recovery given up He feels "justified in assuming the position that in cases of ascites in the female, before the patient has been subjected to the usual practice of repeated tapping with its universally bad results, the most thorough investigation as to the existence of small neoplasms as pathological factors should be made, and if signs of their existence be found, exploratory incision should be made with the folorn hope that relief might be obtained

I can cite two cases of my own, where exploratory incision as a means of diagnosing abdominal tumors, might have been the means of saving two lives 1 A lady of Peru, Ind , under the care of Drs Brinton and Higgins at the time I saw her, had consulted two very eminent operators before consulting me Each insisted that the sound passed ten inches into the uterus, and that therefore it passed into the enormous tumor which distended her abdomen from the pubes to the ensiform cartilage, and hence nothing could be done She had been tapped once and three gallons of fluid drawn from her abdomen During six years she sought the best advice with the view of an operation When I saw her she was already poisoned by sepsis, pulse 140, temperature 103° F I was asked to make an exploratory incision I found a tumor weighing about 23 pounds, displacing the pelvic viscera, and in an advanced state of decomposition It was subserous, pedunculated When I seized it with my hand, my fingers pierced it, dragging away a rotten piece with pus dropping from it as I lifted it up She lived only twenty four hours If an exploratory incision had been made only *one* year before, this life might have been saved, for the pedicle was small and the uterine cavity not deeper than four inches The tumor was exhibited to the Marion County Medical Society, 1885

2 A lady of Hamilton County, Ind , had been cared for by a physician of Noblesville I was asked to see the case with Dr H S Herr, Westfield, Ind We found a distended abdomen suggestive of ascites No operation was made Death occurred soon after I saw her Post mortem determined that the cyst had ruptured, probably six months before death, since the abdomen had been that long distended No doubt was felt that, had an exploratory incision been made in proper time, the patient would have had a fair chance of recovery I cite these two cases in confirmation of Dr Thomas's views of exploratory incision

Dr R S Sutton, of Pittsburgh, the Tait of America, speaks in the following terms of exploratory incision "Make a clean cut down to the peritoneum, divide or tear the latter after making a small opening in it, as one's fancy runs Introduce the requisite number of fingers or the hand, turn out the intestines on a clean towel, look them over for wounds or obstructions, examine a tumor, or tubes, or ovaries, or uterus, or bladder, liver, kidney or spleen Having done carefully, clean out the cavity with gentle sponging or irrigation, carefully return the viscera, carefully close the wound if all has been left clean and the cavity of the peritoneum dry I say, you have done nothing that will kill your patient, but you have cleared up the case, possibly saved a life These measures must be observed if success will follow such practice And when this practice obtains, fewer people will die and fewer will be hanged for

killing them with pistols and knives and dirks People who die now for want of an ante mortem examination will be spared the post mortem, which rarely does the patient any good Such scenes as a hospital staff turning away from a woman dying from the twisted pedicle of a large ovarian cyst will be no more Such practice as is witnessed when a doctor sits by and gives opium till the post-mortem reveals the fact that an intestine was shot or stabbed through, or that an obstruction killed the patient, will vanish "

He thus discusses who should do the work "The best law any practitioner can lay down for himself and his patient in abdominal work is this If you can't do a radical operation under proper precautions, do nothing The patient should be sent to some one prepared for and capable of doing the work In Europe and Great Britain, this rule prevails practically, and hence prominent operators get many cases, and it is from these men that the improvements in abdominal surgery have emanated Simple bush whacking in abdominal surgery is a very poor way to make a reputation All such cases done in a lifetime will rarely exceed a dozen, and if this dozen comprise all the experience the operator gained up to the time of his demise, it has done humanity very little good When the work in this country is put out to the men prepared to do it, and the cases are not bungled from the start, then we will have just as good results as are found abroad When men who have not had special clinical training in abdominal surgery cease to do it, and act for the good of the patient, rather than for something else, then this branch of surgery will do well in this country The present range of abdominal surgery is very extensive The liver, gall bladder, spleen, kidneys, urinary bladder, intestines, ovaries, tubes and uterus are all, under diseased conditions, successfully attacked "

Mr Tait says on the same subject "What I fear, in fact what I already feel, is that the remarkable success which I have had, and of which Prof Byford speaks in such strong terms, is really leading astray those whose opportunities have not been as my own, into the belief that the work is simple, easily acquired, and free from risk It is not so, and unless those who practice it choose to follow me in the rigid precautions and the immense care I give, not only in the mere performance of the operation, but in the surroundings of my patients and to every detail in connection with them, they will not obtain, they must not expect, the success which I have had I have said that I fear, in fact I already feel, that this success of mine is leading people astray, and I want to urge in the name of humanity, as well as for the sake of the art we practice, that there should be less of the indiscriminate rushing into this kind of work which has already been deplored on both sides of the Atlantic "

Indiana women are as worthy of successful abdominal surgeons as are those of any other part of the world Let us remember, then, that those who have placed laparotomy on a solid foundation, were men who had more or less completely abandoned the general practice of medicine, some of them at a great sacrifice, that they might secure that prime element of success in abdominal surgery, a large personal experience in the work Booth would not think of playing Hamlet with new supports each time So those who have published statistics, bad as well as good, demand that their patients shall have specially drilled attendants, whose increased personal experience in the work is a wonderful supplement to the skill and experience of the operator

Dr Sutton has recently published all his abdominal sections including his death roll Dr Goodell comes out annually with his "Year's Work in Ovariotomy," always giving his death roll Dr Wylie is publishing his work with its necrology Dr Homans prints 260 odd operations, embracing fatal cases I visited these men recently and saw them operate They are specialists They are doing for America what Wells, Keith, Bantock, Martin, Schroeder and others did for the statistics of the old world I here report my

TWENTY FIVE CASES OF ABDOMINAL SECTION WITH TWENTY RECOVERIES

In the accompanying table, cases 1, 2, 3 and 4 were reported in Transactions of Indiana State Society, for 1884

Case 5 died from erysipelatous peritonitis, in the City Hospital on the fifth day after the operation The hospital had been built less than one year, still a case of erysipelas had been treated across the hall, only a few days before the operation I was informed of this at the post mortem examination of my patient

Case 6 died in about twenty-four hours after our efforts, from shock She had a violent attack of general peritonitis, in February preceding the operation, from which she came near losing her life After this, the tumor grew rapidly, the operation being a last resort The words yes, under the word recovery, renders comment unnecessary, except that cases 7, 8 and 9 were reported to the Indiana State Medical Society for 1885, and that my reports of work there have encouraged some practitioners to urge earlier operations, and stop tapping, thus insuring better success, and the success removes, to some extent, the fear, heretofore felt by patients in this state, that an ovariotomy was almost sure death Others heretofore silent, on the subject of abdominal surgery, have presented the subject to State and county societies This will aid in educating doctors and patients to the fact that the time for a successful ovariotomy is before the forces of death, plus the operation are stronger than those of life

Case No 20 was really the subject of an exploratory incision, to differentiate between a pelvic abscess and an encephaloid mass It proved to be the latter, the tumor sprang from the left ovary, filled the pelvis, and completely surrounded the rectum, making defecation extremely difficult The growth was not disturbed except to get a fragment for microscopic examination It proved to be typical encephaloid cancer The wound, five inches in length, healed perfectly She recovered *entirely* from the operation, but the rectum completely closed, her death occurring two weeks from the date

TWENTY FIVE CASES OF ABDOMINAL SECTION, WITH TWENTY RECOVERIES

Number	Residence	Medical Attendant	Age	Married or single.	Disease	Operation	Date	Hospital	Private	Recovered	Died
1	Carters Station	Dr Sellers	43	M	Ovarian cyst, 30 lbs	Left ovary removed	Nov 17, 1883		Yes	Yes	
2	Loogoota Ind	Brittain	25	M	Malignant.	Right ovary removed	Dec 20, 1883		Yes		Yes
3	Indianapolis	" Maxwell	18	S	Ovarian cyst	Left ovary removed	April 5 1884	Yes		Yes

of the operation I consider an exploratory incision worthy of record as, in my opinion, it will, in expert hands, be a useful aid in diagnosis, and enable us occasionally to save a human life

This report includes all my abdominal sections, for ovarian diseases My statistics are like those of most operators, *i e*, improved by increased personal experience My experience has been supplemented by that of Miss Clementia M Prough, the nurse who manages my private hospital, and has had charge of the after treatment of my last fifteen cases True, I saw the operation many times before doing it myself, but it is like the juggler who keeps six balls in the air at a time—it looks simple Try it, you will let a few drop Sufficient time has not yet elapsed to determine the *cure* in some of the cases where I removed small ovaries and tubes I have, however, photographs and letters from some of them who were confirmed invalids, which are to me most gratifying, especially considering the fact that our text books, written only a few years ago, consigned these sufferers to a life of incurable invalidism

Your honored president, Dr Kemper, suggested to me yesterday, that the laity were not yet educated to the advantages of early operating, or to the danger of death from delay I replied that the published statistics of men specially equipped for the work, a larger experience by the few and fewer operations by the many, will in America, as in the Old World, show such a low rate of mortality that women will no longer defer an operation, but will accept it early, at the hand of the specialist For, despite reckless operating, and more reckless, almost criminal inexperience of those who conduct the after-treatment of some cases, I predict that this century will close honoring abdominal surgery for its marvelous achievements, not only as the crowning glory of all surgery, but of all science, and all art

MEDICAL PROGRESS

VASELINE IN THE HYPODERMIC INJECTION OF ANTISEPTICS —MEUNIER, of Lyons, considers vaseline as diffusing itself very rapidly through all the tissues of the body, its diffusibility varies inversely with its consistence, which may be that of a perfect liquid or that of wax, it preserves its diffusibility when holding in solution a microbicide Antiseptics dissolved in vaseline, when injected beneath the skin or applied upon a wound or a mucous surface, are diffused without exciting pain or reaction, provided that the substances used be pure and in doses which can be tolerated, the dose and consistence of the dissolvent must be varied according to the organ treated

The method of treatment is as follows Among the antiseptics used in these experiments upon animals were carbon bisulphide, carbolic acid, camphor, iodoform, thymol, essence of cubebs, oil of santal, copaiba, oil of cinnamon, turpentine, thyme, eucalyptus, mint, kousso, and most of the vegetable alkaloids After these solutions had been tried successfully upon animals, they were employed upon men These are the formulæ

Eucalyptol (pure), 5 parts,
Chemically pure vaseline, 20 parts by weight

The injections are made upon the outer side of the thigh The dose tolerated varied from 15 minims to 3¾ drachms and more, daily

Eucalyptol (pure), ɱlxxv,

Iodoform,	℥iv,
Vaseline (pure),	℥x

The dose tolerated is the same as for the first mixture

Carbon bisulphide,	℥xv,
Vaseline (pure),	℥iv¾

Of this mixture, 15 to 30 minims, and more, can be given daily, provided small doses are used

Turpentine, pure (prepared after the method of Berthelot),	℥lxxv,
Vaseline (pure),	℥v

From ℥xv to ℥iiss may be given daily

It is of the utmost importance that these substances should be chemically pure, and that they be given with the greatest accuracy in measuring the doses All impure vaselines turn black in contact with sulphuric acid Most samples of commercial vaseline give the following reaction When saturated with the purest carbolic acid and slowly heated, it becomes rose colored, but deposits a violet precipitate The intensity of the violet color of the precipitate increases on the addition of alcohol, and the color, which is probaly aniline in its nature indicates the presence of nitrogenous impurities which are dangerous, the abundance of the precipitate is in proportion to the amount of impurity present In every test made pure vaseline did not give these reactions, and also gave no pain or reaction when injected into animals Among antiseptics the essences are nearly all impure For example, commercial essence of eucalyptus has a strong odor, an acrid taste, an acid reaction, and boils at 80°, its active principle, eucalyptol, which boils at 175° (Cloez), forms only a third or a half of the commercial article The same is true of turpentine and its essential element, and of other substances mentioned Almost all essences contain resins which should not be introduced into the economy When these articles are mixed with pure vaseline these resins are precipitated, and may be separated by filtration Pure eucalyptol is not precipitated by vaseline To prepare for injection, these antiseptics should be thoroughly shaken with the pure vaseline, allowed to stand, and filtered through two Berzelius filter papers

Experiments upon animals with these solutions were made in the treatment of the following diseases fistulous, fungous, tuberculous, and cystic tracts, favus, herpes tonsurans, alopecia, psoriasis, eczema, acne, and venereal lesions albugo, granular eyelids, glaucoma, puerperal fever Animals were also treated for anthrax, scab, farcy, and tuberculosis, general and local In all the trials made albuminuria was never produced, even when a temperature of 104° F was reached and large doses were given Among many interesting and important observations made was the injection into the lung of a horse of ℥v of a solution of eucalyptol, ℥v of a solution of bisulphide of carbon, without unfavorable reaction, 10 drops of eucalyptol solution were injected into the eye and windpipe of a rabbit, 15 drops into the eye of a sheep, ℥iss under the skin of a horse Pure vaseline was injected in the following heroic doses under the skin of a horse weighing eight hundred pounds

First injection, ℥viss
Second injection, ℥xiv four hours after the first
Third injection, ℥ix ten hours after the second
In all, one kilogramme (about two and one fifth pounds) in twenty four hours

The whole was well borne by the animal, more could have been tolerated, the best point or injection was at the animal's side, diffusion was instantaneous when the point of injection was rubbed with the hand

Regarding the use of impure vaseline, a case is cited in which the injection of ℥xv of impure vaseline, injected into the arm, resulted in phlegmon and the formation of a pint of pus These solutions are also appropriate for the making of antiseptic dressings and the surgeon can thus make for each case the appropriate dressing, as the circumstances of the case indicate —*Bulletin Général de Therapeutique*, January 15, 1887 —*Therapeutic Gazette*, April 15, 1887

CHLOROTIC ANÆMIA —In a paper on this subject DR JAMES KING CROOK summarizes as follows

Our knowledge of the pathological features of chlorosis may be expressed as follows The disease may be said to consist in a temporary arrest of hæmatopoiesis, without fixed or well defined organic changes in the cytogenic, circulatory, or reproductive apparatus The true histological substratum of the disease consists in a loss of the hæmoglobin of the blood This loss is due less to a numerical destruction of the red blood-globules (oligocythæmia) than to a diminution of the hæmoglobin value of the individual corpuscles (oligochromæmia) The remaining constituents of the blood are unchanged

Concerning the causation we may say that this is *par excellence* a disease of puberty, and is intimately associated with the development of the reproductive organs at this period The nature of this connection is not perfectly understood in our present state of knowledge It occurs most frequently in the previously feeble and delicate, and its development is facilitated by imperfect nourishment and pernicious hygienic surroundings

The principal symptomatic phenomena consist of a more or less intense pallor of the superficies, cardiac palpitation and dyspnœa, neuralgia in various situations, headaches, and other neuropathic manifestations The diagnosis rests upon the foregoing symptomatic features, conjoined (in most cases) with certain auscultatory signs in the heart and great vessels, consisting of the *arterial systolic bruit* and the *venous hum* Graver forms of blood disease are excluded by the absence of pyrexia and splenic or lymphatic enlargement

The treatment of chlorosis consists in placing the patient under as good hygienic conditions as possible, in the observation of a nutritious regimen, and especially in the administration of large doses of iron The curative value of ferruginous preparations has been amply attested both by clinical experience and experimental research Other symptomatic indications which may arise are to be met as occasion requires —*N Y Medical Journal*, June 11, 1887

THE AMMONIA TREATMENT OF FEVER

Our readers will remember that in THE JOURNAL of October 10, 1885, we called attention to a paper by Dr S K Jackson, of Norfolk, Va , on the *Ammonia Treatment of Typhoid Fever*, in which this treatment was based on the idea that the most important therapeutic indication in typhoid fever was to supply nitrogenous waste Still more recently was published, in THE JOURNAL of December 11, 1886, a paper by Dr J R Barnett, of Neenah, Wisconsin, entitled *Salicylate of Ammonium in the Treatment of Typhoid and Septic Fevers and Inflammations* His conclusions are too many and long to be repeated here, but his paper, as well as that of Dr Jackson, will repay another reading in connection with the latest contribution to the subject, a paper read by DR J D SULLIVAN, of Brooklyn, before the recent metting of the Fifth District Branch of the New York State Medical Association, on the *Therapeutic Effects of Ammonium Salicylate* Being favoraby impressed with the theories and results presented by Drs Jackson and Barnett, Dr Sullivan determined to give the ammonium salicylate a careful trial

The first case in which he had the opportunity of doing this was one of typhoid fever in a young man He found him presenting a suffused countenance, furred tongue, dry skin, and temperature at 102°, with tenderness over the abdomen and the general characteristics of a case of typhoid fever, the diagnosis of which was further strengthened by the fact that it had occurred in a neighborhood in which Dr Sullivan had a short time previously attended six undoubted cases of the disease After evacuating his bowels with a small dose of calomel, to which was added one grain of powdered ipecac, he prescribed gr viij of salicylate of ammonium, in a solution of glycerine and water, every four hours On the next day he found the temperature reduced to 100°, the skin moist, and the general condition of the patient somewhat improved On the following day the improvement was more marked, and the ammonium salicylate was reduced to gr viij four times a day He continued to improve daily, and on the fifth day of his attendance Dr Sullivan found him dressed and sitting up, nor could any amount of persuasion induce him to return to bed His temperature was normal, and he complained of nothing but weakness He continued to take the remedy in the same dose three times a day, in addition to a tonic containing quinine, and improved so rapidly that within two weeks from the time of the doctor's first visit he was able to return to his business In commenting on this case Dr Sullivan remarked that, while it was well known to the profession that mild cases of typhoid fever are occasionally met with which run a comparatively short course, he could but feel convinced that in this instance the disease was favorably influenced by the special remedy employed While he did not expect to meet with equally good results in every case of typhoid, he thinks that the ammonium salicylate will prove a valuable agent in typhoid fever

In six cases of facial erysipelas he has used it with very gratifying results The temperature was invariably reduced by its administration, and the course of the disease so modified that its beneficial effects were quite evident In all these cases the disease subsided in from four to seven days Among other cases in which he has employed it was one of septic cellulitis of the arm, with profound constitutional disturbance The patient was a butcher of robust physique, 49 years of age The trouble originated from a slight wound on the posterior aspect of the ring finger of the right arm, and about a week after it was received he noticed a painful sensation in the arm, for which he consulted Dr Sullivan On the ulnar surface of the forearm there was found a subcutaneous circumscribed swelling, quite tender on pressure, but free from redness or any discoloration Soon after leaving the doctor's office he was seized with a violent chill, which continued for nearly an hour, and was followed by high fever, with extreme restlessness and anxiety of mind During the next twenty four hours his temperature ranged from 104° to 105°, although he was cinchonized with quinine, which was administered freely with small doses of morphia In the meantime the swelling in the arm had extended very much and assumed an erysipelatous appearance

He now became quite delirious, vomiting set in, and the case assumed a very serious aspect Under these circumstances the use of quinine was suspended, and salicylate of ammonium was ordered in 8 grain doses every two hours After the fourth dose a copious perspiration was induced and the temperature fell to 102°, and he became comparatively comfortable In consequence of the improved condition the remedy was now given less frequently, but he still continued to take it regularly, and under its use the case progressed almost uninterruptedly toward recovery

Dr Sullivan also refers to the use of the remedy, with illustrative cases, in puerperal septicæmia, the third stage of phthisis, diphtheria, dyspepsia with fermentation, infantile diarrhœa and croupous pneumonia, and draws the following conclusions

Ammonium salicylate is certainly a very effective antipyretic It will not reduce temperature as rapidly as antipyrin or antifebrin, but the antipyretic effect is more lasting than that produced by either of these agents

In certain diseases of septic origin it exerts a curative action by tending to retard, and possibly inhibit, the development of septic elements in the system

I cannot agree with Dr Barnett that it is stimulating From my own experience I am inclined to believe that in large doses, or in moderate doses continued for a long time, it has a decidedly depressing effect upon the heart and respiration, but this depression may be obviated by administering it in combination with the aromatic spirits of ammonia

It has an irritating action upon the kidneys, and consequently should not be given in scarlet fever, or in any case in which these organs are not in a healthy condition

It has been my custom to prescribe it in from gr viij–x doses every two to four hours during the first day, then at longer intervals as the requirements of the case may indicate In some cases ʒss given in divided doses during twenty four hours will produce decided ringing in the ears, others will take ʒj in the same time with but little disturbance To children of about 3 years of age I usually administer it in gr ij doses every four hours

RATHER MIXED

The Editor of the *Independent Practitioner*, devoted to Dental and Oral Science, in his comments on "Medical Recognition," in his August number, gets some things so mixed as to suggest the inquiry whether the season of unusual summer heat has not disturbed his cerebral circulation

He commences by copying the *resolution* adopted at the recent annual meeting of the American Medical Association, defining the conditions on which those practicing the special department of Dental and Oral Surgery can be recognized as members of the regular medical profession, and after a few lines of approval, he makes the following singular statement, "*The resolution positively announced* that the possession of such a diploma would entitle its holder to admission to the International Medical Congress" Inasmuch as the resolution, which appears to have been directly before him, not only contained no such *positive announcement*, but actually makes no allusion, either directly or indirectly, to the International Medical Congress, it is difficult to account for such an assertion Yet his next sentence is no less erratic He says "We were not certain that the authority of the American Medical Association to establish *new degrees* in medicine would be respected by all the world, or that its right to modify the rules of admission to a Congress with which that Association had really nothing to do, would be acknowledged by foreign members, etc"

If our readers will turn to the number of the JOURNAL for June 25, 1887, Vol viii, p 722, where the resolution and the action of the Association thereon are recorded, they will seek in vain for the slightest allusion to the establishment of any "new degrees in medicine," or to any modification of the rules of admission to the International Medical Congress whatever And, if it will help to calm the fears and remove the doubts of our editorial *confrère* we will assure him that the resolution which was adopted by the American Medical Association, was not hastily drawn, nor was it brought forth to meet some temporary emergency relating to some Congress, nor yet to serve the interests of any clique, school, or party Its author commenced a quarter of a century or more since, to publicly advocate such measures as were best calculated to reclaim the diseases, deformities and injuries of the teeth and their appendages as a part of the general field of medicine and surgery, and to so educate the dental practitioners as to enable them to take their legitimate place within the ranks of the medical profession The good work progressed so satisfactorily that at the meeting of the American Medical Association in May, 1881, he had the pleasure of uniting with Dr Lewis A Sayre in seconding the motion made by the honored S D Gross to establish a Section of Dental and Oral Surgery on the same basis as the other Sections of that body And being satisfied that the favorable time had arrived, he carefully pre

pared and presented the resolution which was adopted at the meeting of the Association in Chicago in June, 1887, as a fair, safe and practicable method of facilitating the completion of the work of placing the special department of dental and oral science and practice where it legitimately belongs within the domain of medicine and surgery And we hope the editor of the *Independent Practitioner* will waste no more time in looking for some cat under the meal, or in trying to connect a measure which related exclusively to the interest of Dental and Oral Surgery in this country with the International Medical Congress, the terms of admission to which had been fixed two years before and were mainly founded on the precedent afforded by the London Congress of 1881

MR TAIT AND THE GERMAN LANGUAGE

In a recent address on the germ theory and advances in abdominal surgery, MR LAWSON TAIT, indulges in some rather severe strictures on the germ theory, which, with the German language, seems to trouble him not a little It will be remembered that Dr Sanger recently advised Mr Tait to learn German and read the works of German gynecologists Mr Tait says "Unfortunately for me, that is just what I did some twenty years ago, with infinite labor, for the language is neither simple nor easy I have long been convinced that my time in this respect was thrown away " From this it would seem that Mr Tait's knowledge of the German language is as faulty as his pathology Again he says "The German mind, at least the German medical mind, is essentially different from the mind of the Briton It not only evolves from its own consciousness descriptions of things other than the proverbial camel, but it so wraps up its grain of wheat in such a bushel of chaff that the labor of getting a meal is intolerable Nothing pleases it so much as metaphysical speculation, while we, on the contrary, are eminently pragmatic " From this it will be concluded by one acquainted with German medical literature, that Mr Tait has allowed his knowledge of the German language, acquired by infinite labor, to lie fallow since he gained it twenty years ago We do not wish to detract from the practical, pragmatic mind of the Briton, but it must be fairly said of the German mind that it is about as unceasingly pragmatic as anyone could wish We can refer Mr Tait to many German books and articles, hundreds of them, from which he can obtain many a hearty meal of "clean wheat," provided he retains his laboriously acquired knowledge of German And from the frequency with which German writers are referred to in British medical literature we must conclude that his opinion is not shared by many of his countrymen

SINGULAR MODE OF BANKRUPTING THE TREASURY

"It is time for plain language on the *Journal* question With every advantage in its favor *it has bankrupted* the Association's treasury "—*Medical Standard*, June, 1887

The Treasurer of the Association in June, 1883, before a number of THE JOURNAL had been issued, reported the total receipts into the treasury for the year to have been only about $5,000, and the balance then on hand only $903 93 After four years of publication of THE JOURNAL the same treasurer reported the total receipts for the year ending June 1st, 1887, to be $21,723 22, and the balance on hand without a dollar of indebtedness, $1,403 77 by which the Association was enabled to appropriate $1,000 in aid of the Ninth International Medical Congress and yet leave a cash balance in the treasury of $403 77, to which should be added accumulated capital in THE JOURNAL printing office of $1,058 56 We agree with the *Medical Standard* that "it is time for plain language on THE JOURNAL question," but it is also quite as urgently important that the *language* should be as *truthful* as it is *plain*

SANITARY CONVENTION AT TRAVERSE CITY, MICH

Arrangements have been completed for holding a Sanitary Convention under the auspices of the Michigan State Board of Health, at Traverse City, Mich , on Wednesday and Thursday, August 24th and 25th, 1887 At each session of the convention there will be addresses or papers on subjects of general interest pertaining to public health, each paper to be followed by a discussion of the subject treated The public are cordially invited to attend

THE BLANK FORM OF APPLICATION for registration as members of the Ninth International Medical Congress will be found on advertising page 10 of this number of THE JOURNAL Those wishing to be registered in advance of the meeting can fill the blank fully and plainly and send it with the fee, $10, for American membership, to J M Toner, M D , 615 Louisiana Avenue, Washington, D C

AMERICAN RHINOLOGICAL ASSOCIATION — The fifth annual meeting of this organization will be held

in Washington, D C, September 1st, 2d and 3d, 1887 A full programme of papers and topics for discussion has been arranged for the occasion J A Stucky, M D, Lexington, Ky, is president, and P W Logan, M D, Knoxville, Tenn, secretary

SOCIETY PROCEEDINGS.

AMERICAN OTOLOGICAL ASSOCIATION

Twentieth Annual Meeting, held on Tuesday, July 19, 1887, at the Pequot House, New London, Conn

The Society was called to order at 10 30 A M by THE PRESIDENT, DR J S PROUT, of Brooklyn

The report of the Committee of Conference with reference to the formation of *A Congress of American Physicians and Surgeons*, was adopted

DR H KNAPP, of New York, read a paper on

THE EXAMINATION OF THE POWER OF HEARING AND HOW TO RECORD ITS RESULTS

This was the report of a committee consisting of Drs H Knapp, J S Prout and D B St John Roosa The tests for hearing described were the watch, the voice, Politzer's acumetre and the tuning fork The watch is one of the best means of testing the hearing A low ticking watch is of service in indicating the lowest degree of hardness of hearing in those cases where the patient has not become aware of the defect This is, however, not sufficient to measure the higher degrees of deafness In these cases a loud ticking watch or Politzer's acumetre must supply its place Each of these instruments must be tested by the physician in his office on a number of normal ears in order that he may obtain a standard It is a fact that in persons over 55 years of age, a low ticking watch may not be heard when placed over the temporal or mastoid bone if the ear is closed, but will be heard if the ear is open

With reference to the voice, as tests for hearing the whispered voice, the voice of ordinary conversation and the loud voice are used Each observer must test his own voice by the acuteness of hearing of normal persons between the ages of twenty and forty-eight years of age The state of the room as to noise and quiet should always be considered The tuning fork over all parts of the skull is heard louder and longer when the ear is closed than when it is open All tuning forks are heard longer by air conduction than by bone conduction Low tuning forks are heard louder but not longer by bone conduction than by air conduction Departure from these conditions indicate disease

DR SAMUEL SEXTON, of New York It seems to me that sufficient importance has not been given to the varying conditions of the patients themselves I find that in cases of chronic catarrhal inflammation of the middle ear, and also in acute forms of inflammation that there are constantly varying changes in the tension of the drum and in the transmitting mechanism

DR D B ST JOHN ROOSA, of New York I am not inclined to lay such stress as has been done on the variations in hearing from hour to hour in cases of chronic inflammation of the middle ear These variations do occur in cases of disease of the middle ear, but I think they are more marked in disease of the internal ear

DR SAMUEL THEOBALD, of Baltimore As bearing upon the use of the tuning fork, I would mention an observation which I have made in a number of instances and which I have been unable to explain I have noted in certain cases that when I have placed the tuning fork on the vertex the patient will hear it louder in one ear, say the right Then striking the fork again and placing it upon the forehead it will be heard best in the left ear This has given me less confidence in the tuning fork as a differential test between middle ear and labryrinthan troubles

DR H KNAPP In certain cases of chronic catarrh you get no change in the hearing power by any test In these cases I think that nothing is to be looked for from treatment Where, however, by changes of weather or changes in the patients condition, there is a change in the hearing power, we know that there is something to improve We get not only an estimation of the condition, but we also get a foundation for prognosis and an indication for treatment

DR CHARLES H BURNETT, of Philadelphia, reported a case of

SUCCESSFUL REMOVAL OF AN EXOSTOSIS FROM THE EXTERNAL AUDITORY CANAL BY BONE FORCEPS AND CHISEL

The patient was a physician about 30 years of age, in whose right ear the exostosis had been growing for fifteen years and within the past year it had entirely occluded the meatus and caused deafness The growth was about one centimetre in diameter pedunculated and attached to the anterior wall of the meatus just within the outer edge of the tympanic bone Its outer surface was covered with thick and rather insensible skin After a hypodermic injection into the concha of fifteen minims of a 3 per cent solution of hydrochlorate of cocaine, the outer surface of the exostosis was seized by specially devised bone forceps and a piece of the bone tumor cut off About one half the growth was thus removed in successive pieces As the blades of the forceps could not enter further into the meatus and get hold of the remnant of the exostosis, a small chisel a few millimetres in width was placed against the attachment and a blow from a hammer on the chisel knocked off the remainder of the growth *en masse* The operation caused very little pain or bleeding The fundus of the canal and the membrana tympani were covered with a glove finger cast of epithelium This was removed and the hearing found to be normal The ear was dressed with a little iodoform and stopped with cotton There was no reaction and the cut surface of bone on the wall of the meatus at the point of attachment of the exostosis was entirely covered with skin in two or three days Usually drills impelled by the dental lathe have been used to open

the lumen of the canal occluded by exostosis The novelty in this case consisted in the use of bone forceps devised by the author to remove the growth as far as possible and then the use of hammer and chisel to complete the opening

Dr H Knapp had taken considerable interest in the removal of exostosis from various canals To attack them at the apex with the chisel where they consist of ivory bone is most difficult The most efficient way in my experience is to attack them at the base Here the bone may be much softer In the after treatment cleanliness and antiseptic precautions are of the utmost importance

Dr D B St John Roosa read a paper on

THE DIFFERENTIAL DIAGNOSIS BETWEEN AFFECTIONS OF THE MIDDLE EAR AND THOSE OF THE LABYRINTH

There has been some difference of opinion as to our ability to differentiate between affections of the middle ear and those of the labyrinth Many cases usually classed under affections of the tympanum, should be placed among disease of the cochlea or of the acoustic nerve The records of seven recent cases were given in detail These cases were nearly all in the middle period of life when its cares and troubles are most pronounced Such patients often exhibit symptoms of nervous exhaustion These cases may be benefitted by the administration of strychnia, arsenic and quinine Proper hygiene should be employed The universal use of the watch as a test of hearing occasionally leads to false conclusions on the part of the general practitioner who discovers loss of hearing by testing with the watch alone When used alone I regard the watch as insufficient When both the watch and the voice are heard badly there is cause for anxiety Many persons have lesions which cause them to hear the watch and certain other tones badly who can hear the voice well In the opinion of the author those persons who hear conversation better than the watch, who hear better in a quiet room than where there is noise, and who hear the tuning fork better through the air than through the bone, suffer from an affection of the labyrinth or nerve and not from disease of the tympanum, although the latter may be engrafted upon the previous affection The general adoption of this view would save a good deal of local treatment of the naso pharynx and tympanum and greatly simplify and improve our therapeutics As far as the aural condition is concerned, I regard these cases as incurable I think that we can assure these patients that if the general health be looked after carefully that they will never hear so badly but that they can hear in a quiet place This has a good moral effect It makes the patient happier and enables us to dispense with much useless treatment

Dr Roosa also made some

REMARKS UPON A CASE OF CEREBRAL ABSCESS

The patient, a boy of eleven years of age, came under observation May 4th 1887, with a painful swelling over the right ear It was said that the boy had had some trouble with the ear two years before but that there had been no discharge For three months he had tinnitus aurium and vertigo One week before he was seen he had pain in the ear, then this swelling appeared Bone conduction with the tuning fork was better than aerial conduction The hearing power of the left ear was normal Immediately above and in front of the auricle there was a swelling about the size of the walnut This presented fluctuation There was a history that previous to admission to the hospital the treatment had consisted in the use of injections and the insufflation of powders The auditory canal was filled with a white substance which was supposed to be the powder that had been employed The day after admission the patient was etherised and the abscess opened with the removal of half an ounce of laudable pus No fistula was discovered The patient did well for nine days Nausea and vomiting then set in and the temperature went up to 104° The patient sank into a condition of coma and died on the tenth day after admission At the autopsy there was found a cerebral abscess one and one half inches in diameter situated in the tempero sphnoidal loba one half inch from the surface of the brain This was lined with thick membrane The membrana tympani was perforated and the upper wall of the canal was necrotic At the junction of the mastoid and squamous bones there was a spot of necrosis one half inch in diameter The canal and mastoid cells were filled with caseous material

Dr Roosa also reported the history of a case of

SUPPURATION OF THE TYMPANUM OCCURRING IN A PATIENT WITH BRIGHT'S DISEASE

The patient, a woman aged 42 years, was seen April 11, 1887 There was intense pain referred to the left ear which had existed since the day before The hearing was much impaired as a result of a chronic non suppurative inflammation of the middle ear The bone conduction was better than the aerial There was a watery discharge from the left auditory canal Examination of the urine revealed the presence of Bright's disease and the patient died some days later from œdema of the lungs The point which the author made was that although this patient complained a good deal of the mastoid process it was determined there was no lesion requiring operation because of the absence of the characteristic symptom of tenderness at the apex The case was regarded as one of tympanic trouble The post-mortem proved that there was no trouble with the mastoid but acute suppuration of the tympanum occurring in a patient with chronic non suppurative inflammation The patient died from the Bright's disease

Dr Emil Gruening, of New York I have this winter seen a number of cases of abscess In two months I saw seven cases In children I open the abscess and invariably open the mastoid cells I do this especially where the abscess has been preceded by otitis media purulenta In four of the seven cases the mastoid cells were filled with pus In this way through drainage was established and all the patients recovered I saw three cases of otitis media purulenta treated by insufflation of powder, leading to

retention of secretions and death All died of meningitis

DR LUCIEN HOWE, of Buffalo This case calls to mind one which I had in a child where there was a history of recurring attacks of ear trouble with discharge It was stated that good results had been obtained by the use of alum and boric acid This was continued and the patient began to develop the typical signs of mastoid trouble I etherized the child and removed the accumulation in the outer ear, all the symptoms then subsided

DR W H CARMALT, of New Haven The fact that the cerebral abscess was surrounded by a thick membrane does not prove that it was of long duration In a recent case of cerebral abscess resulting from an injury over the parietal bone, I attempted to reach the abscess by trephining, and passed my knife 2½ inches in the direction where I supposed the abscess to be, but got no pus The man died and I found an abscess in about the position I had passed the knife, but the wall was so thick that the pressure of the knife had squeezed the pus into the lateral ventricles and death had been the result In this case the operation was performed within two months of the original injury

(To be concluded)

AMERICAN OPHTHALMOLOGICAL SOCIETY

Twenty third Annual Meeting, held in New London, Conn, Wednesday and Thursday, July 20 and 21, 1887

WEDNESDAY, JULY 20—FIRST DAY

The meeting was called to order by the PRESIDENT, WILLIAM F NORRIS, of Philadelphia

The following were elected to membership Drs J B Emerson, New York, H F Hansell, Philadelphia, J O Tansley, New York, M Haywood Post, St Louis, and Edmund C Rivers, Denver, Col

A Memoir of Dr Ezra Dyer, of Newport, R I, one of the founders of the Society, was read by Dr Hasket Derby, of Boston

The death of Dr William S Little, of Philadelphia, was also reported

DR C S BULL, of New York, read a

REPORT OF THIRTY SIX CASES OF SIMPLE EXTRACTION OF CATARACT WITHOUT IRIDECTOMY

Of these 36 cases 20 were males and 16 females In 24, the cataract was hard and senile, in 11 it was traumatic and soft or semi soft, and in 1 case it was of secondary origin There were corneal mamlæ in 3 cases, tremulous iris in 7, old choroiditis in 5, and irido choroiditis in 1 Careful antiseptic precautions were adopted in all the operations The operation was done with the patient lying in the bed he was to occupy after operation The speculum was employed in every case The knife was long and narrow, narrower than that of von Graefe It was quickly passed across the anterior chamber, the flap measuring about two fifths of the corneal circumference Prolapse of the iris did not usually occur, but if it did, it was allowed to remain until the extrusion of the lens The capsule was then opened by a quadrilateral incision, and by pressure the lens was caused to pass out of the corneal wound If reduction of the iris did not occur spontaneously, it was reduced with a spatula All soft lens matter was washed out with the antiseptic solution (saturated solution of boracic acid), and 1 drop of a solution of eserine (gr j–℥j) instilled The lids are then closed and an antiseptic dressing applied If the eye did well the bandage was not removed for two days, but the eserine solution was instilled twice daily under the bandage At the end of two days the bandage was removed and the eye washed The lids were not opened for four days unless there was some indication for it If, at the end of this time, the appearance was favorable, eserine was reinstilled, and the bandage applied for another day, when it was removed altogether The healing process was usually favorable, there was no suppuration in any case There were 6 cases of plastic iritis of a mild type, and 2 cases of irido cyclitis In the first 30 cases there was no incarceration of the iris In the last 6 cases, in the treatment of which the same care was manifested, incarceration occurred in every one The average duration of the treatment was a little more than twenty days A secondary operation, usually a needling or a laceration of the posterior capsule, was required in 12 cases Prolapse of the vitreous occurred in 4 cases, and dislocation of the lens downward in 2 cases Eserine was not used after the healing of the cornea The degree of acuteness of vision obtained was as follows $\frac{20}{30}$ in 2 cases, $\frac{20}{40}$ in 8 cases, $\frac{20}{50}$ in 2 cases, $\frac{20}{70}$ in 10 cases, $\frac{20}{100}$ in 5 cases, and $\frac{20}{200}$ in 2 cases In one case the eye was blind before operation as the result of irido cyclitis The technique of the operation is more difficult than where iridectomy is performed The knife must be passed rapidly in order to prevent injury to the iris The extraction of the lens is more difficult, and the danger of prolapse of the vitreous is more imminent

DR H KNAPP, of New York During the past year I have performed Panas' operation 68 times Following the operation there was mild iritis in 3 cases, severe iritis with closure of the pupil in 1 case, protrusion of the iris in 3 cases, incarceration of the iris without protrusion in 2 cases, capsulo iritis in 1 case, and suppuration in 1 case This was secondary to an old disease of the eye In 27 cases a secondary operation was performed In 1 case I performed the operation in a man much addicted to drink The operation was successful, but there was slight wrinkling of the capsule In the fourth week I made a simple division of the capsule For twenty-four hours there was not a trace of reaction The following night he had an attack of acute iritis with dysentery, and the urine was loaded with albumen The next day there was circum corneal injection and the ball was very hard Eserine reduced the tension, but did not contract the pupils On the third day the ball was as hard as it is in any case of acute glaucoma I then made an iridectomy and the patient recovered

Dr H Knapp, of New York, then read a

REPORT ON A SERIES OF 1,000 SUCCESSIVE CASES OF EXTRACTION OF CATARACT WITH IRIDECTOMY

These cases were operated on during the years from 1866 to 1886 A tabular statement was given showing the results obtained in each series V = $\frac{20}{200}$ to $\frac{20}{60}$ was considered a good result, V = $\frac{20}{200}$ to $\frac{1}{200}$ was considered a moderate result, and where V = less than $\frac{1}{200}$ the case was regarded as a failure In the first series of cases, the method of extraction was by a very peripheric section, more curved than linear, with the following results good, 70 per cent , moderate, 22 per cent , failures, 8 per cent Of the failures 3 per cent were from suppuration In the second series a peripheric linear section was employed Results good, 86 per cent , moderate, 12 per cent , failures, 2 per cent , all from suppuration In the third series linear section was employed Results, good, 86 per cent , moderate, 9 per cent , and failures, 5 per cent , 3 per cent of which were due to suppuration The fourth and fifth series were performed by peripheric linear section with removal of the anterior capsule Results good, 82 per cent , moderate, 7 5 per cent , and failures, 11 5 per cent , of which 8 5 per cent were due to suppuration In the sixth series, in which peripheric linear incision with peripheric capsulotomy was performed, the results were good, 89 per cent , moderate, 1 per cent , and failures, 10 per cent , of which 8 per cent were due to suppuration The seventh series was operated on by the same method, only the section was less peripheral Results good, 88 per cent , moderate, 7 per cent , and failures, 5 per cent , of which 2 per cent were due to suppuration The eighth series was operated on by circular marginal section with peripheric capsulotomy and with antiseptic precautions Results good, 60 per cent , moderate, 8 per cent , and failures, 2 per cent , of which 1 per cent was due to suppuration The ninth and tenth series of cases were operated on in the same way with the following results good, 90 5 per cent , moderate, 5 5 per cent , failures, 4 per cent , of which 3 per cent were due to suppuration The results obtained, taking the 1,000 cases as a whole, were good, 85 2 per cent , moderate, 9 per cent , failures, 5 93 per cent , of which 3 8 per cent were due to suppuration

Dr J A Spalding, of Portland, Me , read a paper entitled

DOES SUNSTROKE AFFECT THE SIGHT PERMANENTLY?

The author introduced the question of the permanent effects of insolation (or sunstroke) upon vision So many pension claimants are now coming forward, asserting that they suffered from sunstroke and permanent loss of sight in the army, and finally became more or less blind, that it is quite desirable for the expert in examining such cases to be supported by greater authority than he is likely to discover in any text books or accessible literature In point of fact there has never been reported, in the vast extent of ophthalmic literature, but a single undeniable case in which sunstroke has been followed by permanent blindness, and only six others in which the eyes were ophthalmologically examined soon after the attack In all of these optic neuritis was distinctly marked, and in several vision was reduced to a low degree, yet ultimately all six recovered perfect vision without much, if any, treatment Two or three cases illustrative of the assertions of pension claimants were presented in the paper, and the precise reasons for granting or not granting a pension were reported in full Judging from the history of these cases, insolation had nothing whatever to do with the loss of sight, whilst from historical and scientific records it appears extremely doubtful whether the disease ever has any permanent effects on the sight The frequent allegations of patients losing their sight during a sunstroke, or of a dimness coming over their eyes, are simply descriptive of the incipient stages of unconsciousness and are untruthful in a scientific point of view These recollections become, in later years, the basis of pension claimants' assertions that their vision was seriously affected by sunstroke

Dr D B St John Roosa, of New York, reported

A CASE OF PROBABLE QUININE AMAUROSIS

The patient was a young lady who had been living in a malarious district While in Washington she had an attack of intermittent fever Some time after this she was seized with convulsions and unconsciousness It was believed to be a case of malarial coma, and 30 grains of sulphate of quinine were administered by the rectum on four occasions On the third day consciousness was restored, but she was then unable to distinguish light from darkness The pupils were dilated She has been taking quinine and iodide of potassium before I saw her, which was October 18, 1886 Vision was slightly recovered and she could count fingers at four feet On ophthalmoscopic examination the optic papillæ were found small, the vessels very small, but no exudation was seen Quinine three times a day with a hypodermic injection of strychnia was given The dose of strychnia was gradually increased to $\frac{1}{24}$ of a grain and kept at that for some time Vision gradually improved It was at first excentric, but by December 10 she had centric vision of $\frac{20}{70}$ The papillæ were still white and the vessels small The treatment was continued She returned to her home and now states that she can see almost as well as she ever could The urine was tested in this case several times, with negative results

Dr Emil Gruening, of New York In the latter part of June I saw a lady 50 years of age who had been given thirty grains of quinine in one dose When she awoke in the morning she was blind and deaf She was deaf for about twelve hours and absolutely blind for twenty four hours I saw her about five days after the attack The fundus was apparently perfectly normal in both eyes Central vision was normal but the field was much contracted in all directions It does not seem to me that the ischæmia which has been described in the more severe cases, should necessarily be present in the lighter cases of quinine amaurosis

Dr Swan M Burnett, of Washington, read,

CLINICAL CONTRIBUTIONS TO THE STUDY OF RING SCOTOMA

He gave the history in full of two cases of ring

scotoma which he had followed for the space of two years In one case there was a history of syphilis and in the other not, in both there was choroiditis with vitreous opacities In one case there were no gross changes in the choroid, in the other the changes did not correspond with the defect in the visual field In one case only one eye was affected, in the other the affection was binocular In one case the trouble began as a typical right hemianopsia with left semi annular scotoma The central clear spot more or less oval in form, 10°—20°, was never through all the changes diminished in size All who have written on the subject have placed the pathological process inside of the eye, though in none have the changes in the choroid manifest under the microscope been sufficient to warrant such a conclusion and in none have the changes in the form of the visual field been followed so closely or so long as in these cases The course of the nerve fibres in the tract chiasma and nerve as demonstrated by Bunge, Lamelsoker, Leber, Vassius and others, particularly in the somewhat analogous condition of central scotoma which in nearly every instance coincided in form and size with the central clear space in these cases, seems to justify the assumption that the fibres supplying the intermediate parts of the retina were hindered in their function either from a localized neuritis or by pressure of the adjoining parts

DR HENRY D NOYES, of New York A young lady, aged 17, came to me complaining of pain and dimness of sight in one eye The opthalmoscope showed no material lesion, but with the perimeter I discovered a ring scotoma There were no local lesions, no symptoms of brain trouble, and no evidence of hysteria Further examination showed signs of orbital neuritis I based this view chiefly on the fact that pressure of the globe backward elicited unquestionable pain This continued for at least two weeks The ring scotoma subsequently entirely disappeared and vision was restored to the normal I am satisfied that ring scotoma may have an extra ocular origin When we search for these cases more carefully I think that they are not so extremely rare as has been supposed

DR C S BULL, of New York, read a paper on

THE SO CALLED ORTHOPEDIC TREATMENT OF PARALYSIS OF THE OCULAR MUSCLES

The method of Professor Michel was described In this plan the muscle is seized with fixation forceps and the eye ball moved backwards and forwards in the direction of the ordinary action of the affected muscle This procedure produces some pain and slight irritation The pain is largely relieved by the use of cocaine The reader had employed this method in 21 cases of ocular paralysis due to various causes The paralysis was entirely cured in 8 cases, partially relieved in 7 cases and in 6 cases the treatment was entirely valueless

DR O F WADSWORTH, of Boston, read a paper on

RECURRENT PARALYSIS OF THE MOTOR OCULI

Pauline and Francis were twins born of healthy parents In June, 1874, when the twins were three years of age, they had scarlet fever and this was followed by a discharge from the ear In each case a slight discharge from one ear continued In 1877 Frances began to complain of headache which recurred frequently until three months later, when she had convulsions The convulsions were repeated Six months after the first convulsion she complained that she could not see Examination showed well marked optic neuritis The headache and convulsions gradually ceased but she remained blind She was again seen in 1879, and found to be in good health, with the exception of blindness Pauline, after the attacks of scarlet fever in 1874, had headache recurring every month or so On February 24, 1879, she was brought to the hospital with the history that she had suffered with daily pain in the head for two weeks, this was referred to the supra orbital region It would commence about noon, then intermit, recur again about 5 o'clock, and continue for several hours There was vomiting on the first two days of the attack and there was a slight discharge from the right ear She was seen one month later The headaches had recurred every two or three days There was then paralysis of all the branches of the right motor oculi nerve, with ptosis and divergence of the right eye By February, 1887, the headache had diminished in frequency, and for the last few years she has had three or four attacks a year, the more severe being accompanied by ptosis and dilatation of the pupil It was subsequently learned that with each severe attack there was a free discharge of ill smelling fluid from the right ear On May 1st, the right ear was examined and a polypus filling the meatus was found and removed The writer had been able to find only 15 cases of this affection on record Of this number 4 were males and 11 females The period between the attacks was variable and irregular In several cases there was evidently a persistence of a certain amount of paralysis between the attacks This was noted in the case just described There has been no case of permanent relief, and 3 of the cases have terminated fatally

As to the cause of the affection, the results of the autopsies point to a basal origin In one case plastic exudation surrounded the right motor oculi nerve, in another case the right oculo motor nerve was pressed upon at its point of emergence from the crus cerebri, and in the third case there was a fibro chondroma which had developed in such a way as to separate the fibres of the right oculo motor nerve without destroying them In the case reported, the speaker thought that there was an evident association of the paralysis with the chronic aural trouble

DR J A LIPPINCOTT, of Pittsburg, read a paper on

HYPERÆMIA IN MUSCULAR INSUFFICIENCY

The speaker reported several cases of localized hyperæmia of the eye which he thought were due to weakness of the muscles The grounds on which he based this view were the form and location of the spot of hyperæmia and its disappearance, along with other evidence of the muscular insufficiency *(To be concluded)*

FOREIGN CORRESPONDENCE

BERLIN AND HALLE [1]

German Congress of Surgeons—Volkmann's Clinic—Antiseptics in Compound Fracture, Dry Dressings—Candidates in Full Dress—Reform in Study and Teaching—Tuberculosis of Bones and Joints—Subcutaneous Osteotomy—Volkmann—Ohlshausen—Vesico-Vaginal Fistula—Gengmer

My Dear Doctor Fenger—I visited Berlin for the special purpose of attending the meeting of the German Congress of Surgeons, which convened in that city April 13, and lasted for four days You have undoubtedly read abstracts of the transactions in the medical journals, and I will make no attempt to give an account of the proceedings, but will limit myself to a few critical remarks I have been a member of the Congress for a number of years and always waited anxiously for the annual volume of Transactions, but this was the first time I had had an opportunity of meeting its members face to face A personal acquaintance always adds more interest to the literary productions of a writer or author, and it afforded me a great deal of pleasure to form personal acquaintances with men whose names had become familiar to me in German literature From the votes taken for the election of officers I think about 150 members were in attendance, and among them many whose names have long ago found a permanent place in surgical literature Among the most distinguished members present I will only mention Volkmann, Esmarch, Bergmann, Bardeleben, Rosenbach, Schœnborn, Wolfler, Gurlt, Kocher, Socin, Bruns, Hahn, Kummel, Mikulicz, Madelung, Trendelenburg, Kuester, Kovács, Israel and Julius Wolff The first evening was devoted to an informal reception at the Hotel du Nord, where old acquaintances were renewed and new members introduced, after which many met again in a favorite beer saloon where a superior quality of an infusion of hops imported from Munich, was freely patronized I understand that these informal gatherings are usually prolonged until 1 or 2 o'clock in the morning, and yet I always found the members ready for work early the next morning The permanent president, the founder and idol of the Society, B von Langenbeck, was unable to attend on account of ill health, which made the first vice-president, von Volkmann, the presiding officer You will be sorry to learn that Volkmann's health has been seriously impaired, as I believe, mostly from overwork He had just returned from Italy where he had been for three months for the purpose of regaining his former activity of body and mind, but his whole appearance indicates that the object of his visit was not realized, as he looked haggard and careworn It is indeed sad to see such a bodily and mental giant in such a pitiable condition, and all for the sake of science and for the benefit of his fellow men The Congress was formally opened in the Aula of the University by the President, with an eloquent address, in which he alluded feelingly and in beautiful language to Carl Schrœder and other members who died during the last year Professor Billroth and Sir Spencer Wells were elected as honorary members, a just recognition of valuable services rendered science by both of these distinguished surgeons

The programme for this year was a very prolific one as the list of subjects announced contained the titles of at least 20 papers The large number of papers made it necessary to limit the time, and for the last 6 papers only five minutes were allowed for the reading of each That for want of time the discussions were often cut off short can be readily imagined I think it would be profitable for the German Congress of Surgeons to imitate the example of their American brethren, and limit the number of papers sufficiently so that each author has ample time to fully present his subject, to be followed by a free and full discussion by the members Another great fault that prevails here is, that the subjects are not announced always before the time of meeting, so that the members are unable to tell beforehand what topics will be presented and discussed The American Surgical Association requires that each member who is elected to read a paper must not only announce his subject several weeks in advance of the meeting, but he is also expected to furnish the Secretary with a synopsis of his paper, so that when the members receive the programmes from the Secretary they can prepare themselves for the discussions, an example which the German Congress should adopt at once, as by doing so certain important surgical topics annually presented will be fully and systematically treated and will represent not only the views of the writers of the papers, but of all those who participate in the discussions One important feature of all meetings of the German Congress consists in clinical demonstrations of important cases, and in this respect we should learn from the Germans and make our meetings more interesting and profitable by presenting more cases and pathological specimens to illustrate our work At this meeting Sonnenberg showed at least 5 cases of Charcot's disease of the articular extremities of the long bones, Helferich a case of myositis ossificans, Israel a case of cheiloplastic, also a case of rhinoplastic and necessary pathological specimens were exhibited Madelung was the only one who read his paper in full, all the other speakers did not use their manuscript One morning I accompanied a number of the members to the Fridrichshain Hospital where Dr E Hahn, surgeon in charge of that institution, showed us on the cadaver how to perform gastro enterostomy On this occasion I was requested to illustrate my method of performing circular resection of the intestine and of establishing intestinal anastomosis, to which of course I readily consented All present manifested a good deal of interest in the new procedures The day previous to the final adjournment Professor Bergmann was elected by a large majority as President for the ensuing year Although the meeting was protracted for four days I observed, contrary to what we find in America, that nearly all the members remained to the last The German when he undertakes a thing always does it well and comes to stay to the last He considers these meetings as important events

[1] By permission of Drs Fenger and Senn

and will not leave for trivial causes or no causes at all The last day of meeting of all American societies is always slimly attended and at the final adjournment often hardly a quorum is present, an evil which certainly should be corrected

From Berlin I went to Halle, where I arrived April 18 Volkmann's Surgical Klinik is one of the best in the world It is built on the pavilion plan, composed of four sections, each section furnishing accommodations for thirty patients The operating amphitheatre is a model of its kind, and in its construction every care has been taken to make it perfect in its adaptation to antiseptic surgery The crucial test for the value of antiseptic surgery in preventing usual infection has been furnished here if anywhere Volkmann has now treated 300 consecutive cases of compound fractures without losing a single case from septic infection This unparalleled success can only be attributed to antiseptic precautions in the hands of a master Corrosive sublimate and iodoform are the favorite antiseptic agents at present and as a dressing for wounds a small compress of antiseptic gauze is used, over which a large cushion of moss is applied Volkmann places the greatest importance in the use of dry dressings and prefers moss to woodwool or any other substance I visited his clinic for two days and although no major operations were performed I learned many things which will be of great value to me

I found here a relic of the past age in the shape of four young gentlemen in full dress At first I thought they might be waiters in search of a place who had mistaken the beautiful hospital for a hotel or first class restaurant, but on looking at them a second time I detected the infallible sign across their cheeks and foreheads which showed that they were university men, and upon inquiry I was told that they were candidates for graduation It still remained a custom in that city that candidates for graduation during their last semester must appear in full dress These young men were at first objects of curiosity to me but soon became transformed into objects of sincere sympathy One by one they were called down into the forum, and confronted with a case through which they could not look as through transparent glass they became the target of a volley of quick, sharp questions which when not answered as promptly would meet with such encouraging remarks as "Aber, mein Herr, Sie haben mi diesen Morgen noch keine einzige rechtige Antwort gegeben" Do you suppose these young men under such circumstances felt proud of their distinctive dress? Not a bit of it I am sure that when pushed to the wall they would have been willing to amputate the tail end of their dress coats, and for the time being at least, do duty in positions suitable for coats which had undergone such a radical change

Prof Volkmann impressed me as a thorough but hard teacher Certainly, when a man with many scars comes up at the end of his last semester for graduation and cannot answer the simplest questions, there is some excuse for a teacher to become indignant But harsh words at this stage of proceedings will not alter the case If these young men had worked hard, and instead of duelling had spent their time in the dissecting room or the pathological laboratory, there would have been no occasion to wear a dress-coat, in disgrace The trouble with German teachers is that they do all the questioning at the end of the term, after the student has spent perhaps one, two, three or almost four years in idleness Let the professors do as we do in America, submit the students to daily or at least weekly examinations throughout their entire time of study, and the results will be vastly better It is impossible to make up in a few months what should have been done for years There is no question in my mind that the average American student learns more in one month than the average German student in three He learns more not because he has better teachers, or better facilities, but he makes better use of his time I am satisfied that in our last graduating class I had at least a dozen students who, after studying three years, would pass a brilliant examination in any English or German university They would have felt at home even in a dress coat in Volkmann's Klinik passing their final examinations

Volkmann is a firm advocate of early and thorough operations for tuberculosis of bones and joints, but thinks that the time has not arrived when we can render a decisive answer in regard to the prevention of general tuberculosis by the surgical removal of localized lesions He says that scientifically operations are strongly indicated, practically the surgical treatment is still on trial Although he has now performed more than 200 excisions of the knee joint for tuberculosis, he feels incompetent to render a final decision

Among the many interesting cases that I saw was a young man from Finland who came to Halle for the treatment of an anchylosed hip He had suffered from coxitis when 3 years of age, and when the disease finally became arrested it left the hip joint contracted When he came under Volkmann's care the foot on the affected side could not be brought within ten inches of the ground The limb was greatly atrophied and hip joint the seat of bony anchylosis Subtrochanteric osteotomy was performed and, as the thigh was also greatly adducted, the adductor muscles were divided at the same time For months no attempt at union was observed at the seat of osteotomy, and no improvement in this direction took place until H H Smith's splint was applied and the patient allowed to walk around Soon after this treatment was adopted callus formation commenced to take place, and now, more than a year after operation, an abundant callus marks the place where the bone was divided, and perfect bony union will be the result The limb is now only about three inches shorter than the opposite one, and with a high sole the patient will soon be able to walk without artificial support In dividing the adductors of the thigh, the sterno cleido mastoid, and some other deep-seated muscles, Volkmann prefers the open section to subcutaneous division, as the antiseptic treatment prevents complications, and through an open incision the opposing tissues can be more thoroughly and safely divided

Although Volkmann is only 57 years of age, I fear that his scientific career is near at an end on account of ill health His work has been well done He can afford to rest Let us hope that his health may improve so that he may enjoy the fruits of his labor He will continue to live and to work through his numerous pupils and a grateful profession

A visit to Professor Olshausen and his gynecological and obstetrical wards satisfied me that the principles of antiseptic surgery sown in such close proximity had taken deep roots and had thoroughly developed in a new sphere of usefulness Both the gynecological and lying in wards are perfect specimens of ordinary and surgical cleanliness, and consequently indigenous cases of puerperal sepsis are almost unheard of Professor Olshausen has been elected to the important and responsible chair in the Berlin University recently rendered vacant by the death of Professor Schroeder He showed me a number of cases of abdominal section which had been recently performed, and all the patients were doing well

I witnessed an operation for vesico vaginal fistula The opening, large enough to introduce the tip of the little finger, was located near the anterior lip of the cervix uteri The margins were vivified with the knife, and the edges carefully approximated and coaptated with four deep and four superficial silkworm gut sutures The impermeability of the wound was tested by injecting milk into the bladder Antiseptic drainage of the bladder through the urethra was established by inserting a short hard rubber tube to which was attached flexible rubber tubing, the distal end of which was kept in a dependent position and under a carbolized solution An iodoform tampon was placed in the vagina Professor Olshausen has not used silver wire for twenty years, and now uses in such operations exclusively silkworm gut sutures

When I visited Professor Geugmer at his house I found him celebrating his birthday in the company of a select number of friends, but he appropriated at least one hour of the festive day for my benefit, and we spent the precious time in a profitable and interesting way in the discussion of select surgical topics He has a large and remunerative private practice, and is one of the teachers of surgery in the University Professor Geugmer is well known as a teacher and writer, and at the last meeting of the German Congress he read a paper of great practical interest on a special form of hernia, which, after it has been printed, should be read by all surgeons who wish to keep themselves posted on this intricate subject

N SENN

LETTER FROM VIENNA

(FROM OUR OWN CORRESPONDENT)

Tuberculosis of the Conjunctiva—Surgery of the Biliary Ducts—Section of the Third Branch of the Fifth Nerve in a case of Neuralgia, with Recovery—Effect of Caffein, Theobromin and Xanthin on the Muscles—Professor Farkas

At a recent meeting of the Imperial Royal Society of Physicians of this city, Professor v Reuss showed an interesting and rare case of tuberculosis of the conjunctiva The patient, aged 66 years, suffered from a chronic tuberculosis of the apices of the lungs His father died of phthisis, and one of his brothers suffered from pulmonary tuberculosis The right eyelid of the patient was covered with flat and round granulations, and an ulceration 12 mm in diameter covered with granulations was also to be found on the edge of the eyelid In the part of the ulceration which had been removed for the microscopical examination, giant cells and a great number of tubercle bacilli were found Prof v Reuss stated that at first sight, without the microscopical examination of the ulcer, the affection might have been confounded with many others, as, trachoma, tuberculosis, epithelioma, lupus, and so on, but that all conditions except tuberculosis and lupus could be excluded

As to a lupous affection of the conjunctiva, it was a very rare disease, and moreover, if we had to deal in this case with such an affection, this ought to be present also on other parts of the organism Hence, taking into consideration the history of the case, the course of the disease, and the result of the microscopical examination, we must diagnose in the case under consideration a tubercular affection of the conjunctiva

At the same meeting, Professor Hofmokl showed two women on whom he had performed cholecystotomy with a very favorable result In the first case he performed cholecystotomy in February, 1885, and removed twenty biliary calculi from the opened gall bladder, there resulted a fistula which he afterwards closed No symptoms of cholelithiasis had been observed during the two years, and the patient was perfectly well In the second case, on which he had operated three weeks previously and had removed two biliary calculi of the size of a pigeon's egg, the patient was doing well Prof Hofmokl discussed the different conditions occurring in the biliary ducts which required operation, mentioned the difficulty of an exact diagnosis in some of these cases and the different methods which had been followed in the operations on the gall bladder In cases in which the diagnosis of the biliary affection was difficult, one had thought of performing the explorative-puncture of the gall bladder, or the explorative-incision According to the opinion of Prof Hofmokl, however, the puncture of the bladder had to be avoided as much as possible, as it might be very dangerous when there was empyema of the bladder, he preferred in such cases the explorative incision, as this caused no danger at all, when performed under strict antiseptic rules As to the method of operation, he preferred to first suture the bladder to the peritoneum and then open it, whereas Langenbuch gives preference to the extirpation of the bladder Langenbuch had, since 1882, performed this operation six times with five recoveries The unfavorable result in one was due to a calculus which had perforated the cystic duct, after this had been ligatured Prof Hofmokl remarked that it would be better to follow a third method, viz, to ligature the cystic duct, to open the gall bladder and suture it to the abdominal walls The opening of the

bladder by means of caustic paste was not to be recommended, except in cases in which there were adhesions or empyema Respecting the question as to whether cholecystotomy or cholecystectomy was to be preferred, he said that the method which must be followed depended on the respective case When the gall bladder was moveable, and the cystic and choledochus ducts were free, the extirpation of the bladder was indicated, but when there were stony adhesions, the resection should not be resorted to Forty five operations on the biliary ducts had been preformed hitherto, of these, 21 cases owing to empyema of the bladder, 15 recovered, 5 completely and 10 with fistulas Prof Hofmokl remarked at the end of his account that he brought forward his cases before the Society with the intention of inviting the other surgeons to communicate their experiences in this matter, so that reliable statistical data might be obtained as to the results of the operations on the gall bladder

Dr Salzer, assistant to Prof Billroth, showed a man who had been affected since 1883 with a severe neuralgia of the fifth, and in whom all medicinal treatment had no effect at all Galvanization as well as the repeated sections of the buccinator and the zygomatic nerves gave no relief The ligaturing of the left common carotid artery which had been performed by Prof Billroth himself had no effect whatever Dr Salzer, therefore, with the consent of Prof Billroth, tried to relieve the patient of his great pains by performing a resection of the whole third branch of the fifth, the inframaxillary nerve, close to the foramen ovale He, for this purpose, first made a curved incision in the skin over the zygoma, laid the temporal bone bare, and penetrated as far as the foramen ovale The hæmorrhage in this operation was insignificant, only a small muscular branch of the temporal artery had to be ligatured The nerve was then isolated from its surrounding parts and from the arteria meningea media and cut through with the tenotem from behind to forwards He then closed the wound except a small opening through which, in order to prevent adhesions, he introduced a piece of iodoform gauze as far as the foramen ovale, which was allowed to remain there 15 days The great pains soon disappeared, the injections of morphia could be left off, and no typical attack of "tic douloureux" had occurred since the operation As to the sensibility of the skin of the left side (corresponding to the side on which the operation had been performed), he found on examination that the sensitive paralysis corresponded almost to the extent of the territory which was supplied by the third branch of the fifth The highest degree of diminution of sensibility was to be found over the foramen ovale, in front of the ear, at the point where the auriculo temporal nerve made its exit from the skull The sensibility of the mucous membrane of the mouth, as well as that of the netherlip and that of the gums was impaired, this was also true of the left side of the tongue As to the sensibility of taste, no difference could be observed, which was an evidence that chorda tympani had not been injured Dr Salzer recommended this operation in desperate cases, although the permanent result was still questionable, as it involved no danger for the life of the patient

Docent Dr Paschkis and Dr T Pal, working in the laboratory of Prof Stricker, recently made an interesting communication as to the effect of caffein, theobromin and xanthin on the muscles They experimented on frogs in the following way One leg of the frog was ligatured close under the hip joint, and an aqueous solution of one of the drugs under consideration was subcutaneously injected into the back of the animal After a certain interval they quickly laid bare the gastrocnemius muscle as well that of the ligatured sound leg as that of the poisoned one, and fastened them to the kymographion The results which they obtained are The irritability of the muscle of the frog is first considerably augmented by small doses of caffein (Trimethyl xanthin), theobromin (Dimethylxanthin) and xanthin, and then disappears entirely (and after a certain interval of time disappears entirely) This interval is the shortest in caffein, and the longest in xanthin The course of the muscular contractions has in all three drugs one equal typical character, viz a rapid perpendicular elevation and a slow gradual decrease of the kymographic curve The condition of contraction of the muscle is the longest in caffein, the shortest in xanthin As the xanthin possesses the weakest effect, and the caffein the strongest, we might suggest that the effect in this group of drugs is gradually enhanced in proportion to the number of the methyl groups which enter into the primary chemical body

Prof Ladislaus Farkas, surgeon to the Elizabeth Hospital of Budapest, has recently signified his intention to attend the International Medical Congress in America He was a surgeon in the Servian war, and the instruments he has devised for war surgery have gained him great popularity in this country, besides he has a great reputation as a bold operator He expects to remain six weeks in America

DOMESTIC CORRESPONDENCE

MORPHIA AND ATROPIA IN HAY FEVER

Dear Sir —An article on "Hay Fever," in THE JOURNAL of July 23, is likely to convey the false hope that the remedy therein given will prove efficacious In the prize essay the author fails to mention that the ℞ morphine and atropia originated with Dr Morehead, of England, who published it in the *British Medical Journal*, and which went the round of American journals It is not my purpose to discuss the merits of the article, but as the title, "prize essay," may lead a number of your readers to try the remedy I, a sufferer from hay fever, have given it personally a most fair trial, and in my case, as well as those of several of my patients, it has proved the greatest disappointment SUBSCRIBER

New York, July 26, 1887

Dear Sir —The above letter, criticising my paper

on "Hay Fever," almost answers itself The complaint, that I did not give credit to the gentleman who first used morphia combined with atropia, is not pertinent, inasmuch as the purpose of the paper was not to give a history of the various drugs recommended, but to give the Hay Fever Association the results of my study of the disease "Subscriber" does not say that Dr Morehead, of England, preceded me in the use of morphia and atropia, combined, as I recommended, for hay fever I do not know that he did I believed that I was the first to discover the efficacy of this prescription in hay fever, although I did not so state in the paper I have used this prescription for several years successfully, not knowing that any one else had employed it except through my advice Evidently the new members of the United States Hay Fever Association had not heard of Dr Morehead's use of this prescription, for it is not mentioned in the Association's long list of remedies However, if the remedy is efficacious it matters little who first happened upon the discovery, but if it be worthless, as "Subscriber" avers, I cannot understand why he (or she) is so concerned to have due credit given to the discoverer

The fact that any given remedy may prove a failure in the hands of any one medical man, ought not to deter others from giving it a fair trial I am always thankful for honest criticism from competent critics Yours courteously,

SETH S BISHOP, M D

719 W Adams St , Chicago, August 3, 1887

CREMATION AND THE CATHOLIC CHURCH

Dear Sir —The statement in THE JOURNAL of Sept 18, 1886, relative to the position of the Catholic Church on the question of cremation having been discredited, I addressed a letter to Cardinal Gibbons on the subject A copy of his reply is enclosed for your information and that of your readers

Yours, Respectfully,

CHARLES A HARVEY

Washington City, June 29, 1887

C A HARVEY

Dear Sir —Cardinal Gibbons bids me acknowledge the receipt of your letter of the 23d He directs me to say that the Catholic Church discourages cremation as at variance with the practice of the people of God in the old dispensation and opposed to the cherished traditions of the Christian religion

Respectfully, Yours in Christ,

JOHN T WHELAN, *Secretary*

Cardinal's Residence, 408 North Charles Street, Baltimore, June 24, 1887

BOOK REVIEWS

GOUT and its Relation to Diseases of the Liver and Kidneys By ROBSON ROOSE, M D , F C S , etc Third Edition 8vo, pp xii—164 London H K Lewis, 1887

The seven chapters of this valuable little book are devoted to General Considerations with regard to Gout, Sources and Places of Origin of Uric Acid in the System, Theories as to the Nature of Gout, Causes of Gout, Irregular Manifestations of Gout—Visceral and Cutaneous Affections, Hepatic and Renal Disorders connected with Gout, and the Treatment of Gout and of various Disorders connected with it Of these chapters no one is more interesting or useful than that on the irregular manifestations of gout, to which too little study has been given If anything, it could be wished that this chapter was longer

This book is a comprehensive exposition of the subject, well written, and the reader is at all times convinced that it was written because the author had something to say The chapter on treatment is of great value, and he must be unusually well informed who can learn nothing from it

OUTLINES FOR THE MANAGEMENT OF DIET, or, The Regulation of Food to the Requirements of Health and the Treatment of Disease By EDWARD TUNIS BRUEN, Assistant Professor of Physical Diagnosis, University of Pennsylvania, one of the Physicians to the Philadelphia and University Hospitals, etc 8vo, pp 138 Philadelphia J B Lippincott Company, 1887 Chicago W T Keener

There are many books on diet for the sick in our literature, but very few which contain any good advice on "Regulation of Food to the Requirements of Health in Different Periods of Life," which is the subject of Dr Bruen's second chapter And there is one paragraph in this chapter which should be framed and posted conspicuously in every house in the land " No stimulating drinks of any kind should be used by the young or growing persons Milk or water or dilute cocoa should be the only beverages Coffee and tea may thus be reserved for later periods of life, when their stimulative properties may support the nervous system, whereas, if the patient has been overstimulated while formative forces are at work, it is often impossible to prevent the development of an irritated and unbalanced state of the nervous system, which many persons notice in young children, without understanding the cause or how easily the trouble might be obviated "

That portion of the third chapter, "Special Plans for Diet," which deals with infants' foods is replete with information and good suggestions, but some space should have been devoted to the necessity of giving water to infants, especially in hot weather Beef tea and broths are discussed, but we find no mention of meat extracts and but little of meat juice

As the title implies, we find in the book only outlines for the management of diet, and in so small a work one could not expect to find a complete treatise on diet and alimentary hygiene It is the third of a series of "Practical Lessons in Nursing" now being issued by the publishers The author has given us very satisfactory outlines for the management of diet, both in health and disease

INTERNATIONAL CONGRESS.

FUNDS FOR THE CONGRESS

To the Medical Profession

The local Committee of Arrangements have the pleasure to announce to their American brethren that the widespread desire to attend the Congress is such that the amount of money for the reception and entertainment heretofore deemed sufficient, will be entirely inadequate to provide for the large number that will be in attendance They are therefore constrained to appeal to their brethren throughout the country for additional subscriptions to the entertainment fund They feel that to their patriotic countrymen it is only necessary for the fact to be stated in order to secure the sending of such liberal contributions as will ensure the entire success of the social features of this great International gathering, on a scale commensurate with its dignity and importance Let all Americans come to the front and ensure to *all* the foreign members the full measure of the hospitality of free America Contributions should be immediately forwarded to Dr C W Franzoni, member of the Finance Committee for the District of Columbia

By order of the Local Committee of Arrangements

C H A KELLINSCHMIDT, *Secretary*

Washington, D C July 30, 1887

Medical editors, friendly to the good cause, will confer a favor by publishing this appeal [LD]

EXCURSION RATES TO CALIFORNIA

DR LISTON H MONTGOMERY

Dear Sir —I have been repeatedly asked by gentlemen of the medical profession, who will attend the International Congress at Washington, in September next, what would be the cost of a trip to California In reply I wish to say that an excursion to California will be had after the adjournment of the Congress Parties can take the route via New Orleans, returning via the Central Pacific Railroad, thus enabling the excursionists to see a large part of the country at a cost of a little less than the fare one way You may inform all who inquire that a low rate will be made This trip would be especially beneficial to the physicians from Europe, and also to those who have never visited California

Respectfully,

H M VAN ARMAN, T P A S P Co

Chicago, July 28, 1887

NOTE—Dr L H Montgomery assures us that at a later date than the above he was authorized by Mr Van Arman to state that the round trip either from Washington or Niagara to California and return, would be made at about $90, or less than the usual railroad fare one way, and that the Pullman sleeping cars for the trip would be $14 in addition These terms are offered alike to the foreign and American members of the Congress Tickets will be good for 60 or 90 days

EXHIBITS AT THE CONGRESS —All applications for space for Exhibits before the International Medical Congress should be addressed to Dr D C Patterson, Treasurer of the Committee of Arrangements and Chairman of Sub committee on Hall and place of meeting of Congress

MISCELLANEOUS

OLIVER WENDELL HOLMES HOSPITAL —This elegantly appointed hospital has been recently opened at Hudson, Wis The names of the physicians on the staff are an assurance that good work will be done Dr Irving D Wiltrout is the physician in charge, and Dr C C Dix resident The design of the hospital is to treat acute and chronic diseases, nervous diseases being a specialty

NEW YORK CITY BOARD OF HEALTH —Dr R S Tracy has been made Chief Inspector in the Sanitary Bureau, Dr Cyrus Edson Chief Inspector of Food, and Dr William Bullard Chief Inspector in charge of the work of the Sanitary Police

THE CONGRESS FUND —At its recent meeting at Crab Orchard Springs, Ky , the Mississippi Valley Medical Association contributed $250 towards defraying the expenses of the Ninth International Medical Congress

SANITARY CONGRESS IN SOUTH AMERICA —The Government of Peru has invited the republics of Central and South America to cooperate in a Sanitary Congress to be held in Lima on November 1

STATUE OF GUISLAN —A statue to M J Guislan, the eminent alienist has been recently unveiled at Ghent

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JULY 23 1887, TO JULY 29 1887

Col D L Magruder, Surgeon, granted leave of absence for one month, to take effect on or about August 10, 1887 S O 170, A G O , July 25, 1887

Par 13, S O 167 A G O , assigns Lt -Col A Heger, Surgeon, to duty as member of Army Retiring Board convened at Governor's Island, New York Harbor, N Y , vice Col Chas Sutherland, Surgeon, hereby relieved

Major D G Caldwell, Surgeon, order relieving him from duty at Ft D A Russell, Wyo , and assigning him to duty at Ft Assiniboine, Mont , is revoked S O 168, A G O , July 22, 1887

Major P J A Cleary, Surgeon, ordered to Ft Assiniboine, Mont , instead of Ft D A Russell, Wyo S O 168, A G O , July 22, 1887

Capt S G Cowdry, Asst Surgeon, granted one month's leave, to take effect on or about July 24 S O 79, Dept Texas, July 13, 1887

Capt H G Burton, Asst Surgeon, sick leave of absence extended three months S O 171, A G O , July 26, 1887

Capt E T Gardner, Asst Surgeon, ordered for duty at Ft Reno, Ind Ter S O 170, A G O , July 25, 1887

First Lieut C S Black, Asst Surgeon, ordered for duty as Post Surgeon, Ft Bliss, Tex , during the absence, on leave, of Capt S G Cowdry, Asst Surgeon S O 79, Dept of Texas, July 13, 1887

First Lieut W D McCaw, Asst Surgeon, ordered for temporary duty at Ft Riley, Kans S O 78, Dept Mo , July 25, 1887

CORRIGENDA

In the article on Hay Fever, in THE JOURNAL of July 23 p 106, 2nd line from top of second column, read 'not only *not* benefit." Thirty-fifth line read *inferior* for interior Forty second line read *egetatiers* for vegetation

ORIGINAL ARTICLES

THE MANAGEMENT OF OCCIPITO-POSTERIOR POSITIONS

Read in the Section on Obstetrics and Diseases of Women, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY L. CH BOISLINIÈRE, M D , L L D ,

OF ST LOUIS MO

I shall premise my remarks by stating the well established obstetrical fact, that in 20 labors, the vertex presents 19 times The great Naegelé has demonstrated that in about one third of the cases of presentation of the vertex, the occiput was found in the posterior part of the pelvis, and in this position oftenest at the right posterior sacro iliac synchondrosis, occasionally it is found placed at the left sacro iliac joint, or in the hollow of the sacrum, and to sum up, the occiput is found seventy times at the left anteriorly, and twenty seven times at the right posteriorly, the other varieties of position being very rare This opinion has been adopted by most authorities in midwifery Seeing the frequency of this position, it is of the utmost importance to the accoucheur to study its mechanism and treatment

Causes —The chief condition of its production, as shown by Lusk in his admirable treatise, is a partial extension of the head, the forehead then turning anteriorly, in accordance with the law that "the most dependent portion of the presenting part is moved to the front "

Diagnosis Before Labor By Palpation —The vertex is easily recognized, but it is to the left, that the hand which depresses the abdominal parietes meets the greatest resistance, and penetrates less deeply, on account of the protrusion of the forehead on a level with the left ileo pectineal eminence Therefore, the back must be looked for to the right, and to recognize it distinctly, the patient should be placed on her left side, in order to be able to palpate the postero lateral region of the uterus (Pinard, Charpentier)

Diagnosis by Auscultation —According to Depaul, the maximum of the fœtal heart will be heard in the vicinity of the quadratus lumborum muscle, on a line from the right sacro iliac synchondrosis to the umbilicus

Diagnosis by the Touch —The head will be found in a state of semi extension, the posterior fontanelle is back, very high and difficult to reach The anterior fontanelle, in front and to the left, is easily reached Sometimes, the superciliary ridges and even the orbits can be felt, but they will reascend during a pain The nearer the centre of the excavation will the posterior fontanelle be felt, the more favorable will the prognosis be

After delivery, a marked prominence of the frontal bone, and a red mark there, will often be noticed This protrusion is produced by the more dependent position occupied by the forehead, the red spot by the prolonged pressure of this bone against the pubis These signs may serve to verify the diagnosis after the labor

A diagnostic symptom which I have often noticed in my practice is a premature discharge of the amniotic fluid before labor pains have begun

Prognosis —It is generally favorable, and in the majority of cases, the occiput comes spontaneously to the front But it must not be forgotten that this labor is much more painful to the mother and more dangerous to the child, on account of the great extent of the rotation necessary to bring the occiput to the pubic symphysis, and for this reason frequently requires assistance

In the minority of cases, where the rotation forward does not take place, and the occiput is born in an occipito sacral position, there is great danger of laceration of the perineum, or this may be centrally perforated, and the child born through the rent, as recorded by Velpeau, and as in a case I saw in consultation where, by a timely application of the forceps assisted by manual compression, the head was made to reenter the vagina and safely delivered The opening closed spontaneously

Mechanism of these Positions —In occipito posterior positions, how does the rotation of the occiput take place? It requires for its production sufficient uterine action, a resistant pelvic floor, a normally incurvated sacrum, and a normal condition of the ischiatic spines In fact, the rotation of the occiput forward is performed in accordance with the principle of the known geometrical theorem of the parallelogram of forces, through which, when two forces are acting on a moveable body in different directions, this body moves in the direction of the diagonal of those forces For instance, if a cherry stone be pressed between the thumb and index finger, it will fly off by a tangent which is the diagonal of the two opposite forces represented by the thumb and index finger

In this manner the occiput, acted upon by two opposite forces, viz the uterine contraction and the resistant pelvic floor, will be propelled forwards towards the anterior part of the pelvis

Why does not this anterior rotation always take place? It is because there is insufficient uterine action, a lax perineum or one lacerated in a previous labor, a flat sacrum, or abnormally projecting ischiatic spines If any of these conditions be present, there will be no anterior rotation of the occiput, and the labor may be indefinitely prolonged unless terminated by art

But, if all the factors favoring anterior rotation are present, viz uterine contraction, resistant pelvic floor, normal incurvature of the sacrum, and there be a marked projection of the spines of the ischium, or the child very large, then the rotation will take place backwards This abnormal projection of the ischiatic spines can be easily detected through the lateral vaginal walls at about two inches above the pelvic floor The detection of this projection will serve as a means of prognosis as to the course the occiput will take

When the rotation takes place posteriorly, the head descends in a state of forced flexion, the occiput against the sacrum, the forehead against the pubic symphysis, the occiput, following the postero lateral side of the pelvis, turns completely back, is delivered first, and the perineal comissure serving as a fulcrum to the neck, the head being completely extended, there appear successively under the pubic arch the bregma, the face and the chin

Conversion of an Occipito-Posterior Position into one of the Face —This may be spontaneous or produced with the forceps In this instance, the extension of the head becomes quite exaggerated, and the chin is first born under the pubic arch This conversion can take place only if the pelvis in a multipara be unusually roomy, the child small, the perineum lax or torn in a previous labor

Indications —When the labor is prolonged, painful, and there is no tendency to a spontaneous anterior rotation, other indications being present, such as exhaustion of the woman, eclampsia, hæmorrhage, weakness and irregularity of the fœtal heart, showing suffering and danger to the child we must then act promptly We should not expose the patient and child to the dangers of a forced rotation, but without hesitation rotate with the forceps the occiput back, and deliver it at the perineal comissure, with the precautions indicated below

Treatment —In the occipito posterior position, the labor may be terminated normally in two ways Either the occiput rotates spontaneously forward, and the case does not differ from one where the occiput at first corresponded to a cotyloid cavity, except in the duration and extent of the movement of rotation, or the occiput may rotate backwards towards the sacrum The obstetrician may imitate these two modes of delivery But, as the spontaneous termination of the labor in an occipito-posterior position is more favorable to the mother and child, it should be preferred Whenever the occiput shows a tendency to rotate forward, the obstetrician may select this mode of delivery with forceps whenever possible Other modes may be tried, such as rotating with two fingers, pressing back of the child's ear (Tarnier), or palpation These methods will usually fail Some high authorities teach that the occiput should always be delivered posteriorly Among these are Stoltz, Naegelé, Pajot and Cazeau Others teach that the occiput should always, when possible, be brought forward Such is the opinion of Smellie, Depaul, Charpentier, Blot, Tarnier and his pupils

The objections advanced against this method is the danger to the child on account of the great torsion of its neck, the anterior rotation requiring three-eighths of a circle to bring the occiput from the sacrum to the pubis Tarnier has instituted experiments to prove that this torsion does not take place in the neck, that it extends to all the cervical and some of the dorsal vertebræ Still, these authorities admit that there is torsion of the neck, but they claim that clinical facts prove the safety of the method

As for ourselves, we prefer the disengagement of the occiput posteriorly on account of the safety of the child, moreover, Lusk pertinently says that the attempt at performing an anterior rotation of the occiput usually fails Such has been the result of my experience, and I have adopted the practice of delivering the occiput posteriorly whenever the labor had been prolonged, is painful, and no tendency exists at anterior rotation Performed with great care this delivery is safe for the mother and child, in spite of the dread of a lacerated perineum This danger will be avoided by following in this delivery the following rules

The technique of forceps application in right occipito posterior position and in occipito sacral position In occipito sacral position the forceps, applied as in an anterior position of the occiput, the biparietal diameter is then parallel with the transverse diameter of the pelvis, and the occiput occupies the posterior part of the pelvis The left blade is applied to the left side of the pelvis, the right blade to the right side Here is an exception to the rule that the concavity of the instrument should always be applied to that part of the head which is to be directed towards the pubic symphysis, viz the occiput This is a direct and regular application

The forceps properly applied in the right occipito-iliac position, obliquely, must grasp the parietal bosses very firmly, else on the attempt at flexion the blades will surely slip forward towards the child's face, lose their hold and the needed flexion will be impossible, moreover, this slipping forward of the forceps may cause the blades to seriously cut the walls of the vagina Rotate the occiput in the hollow of the sacrum, before making tractions

The tractions are make backwards in order to bring the head to the pelvic floor When it has reached it, begin the movement of forced flexion, tractions quite upwards until the occipital protuberance clears the posterior commissure, then the forceps must be lowered towards the mother's anus and the child delivered by extension, the chin, face and bregma successively passing under the pubic arch

By this forced flexion, the vertex clears the posterior commissure by the sub occipito bregmatic diameter, which is three and three quarters inches, and by the final extension by its trichelo bregmatic diameter, also three and three quarters inches, both being safe diameters, and safe to the perineum

Thus will the perineum be moved If much distended, when a laceration appears imminent, episiotomy should be thoroughly performed To avoid laceration of the perineum, especially in a primipara, a small but most useful operation is episiotomy But the incision, in order to be of any assistance, should be made not *transversely but obliquely* on both sides of the vulva, thus cutting through the transversus perinei muscle The incision should be performed with scissors or blunt pointed bistoury and at least half an inch in extent A few hours after labor, these incissions will have contracted to the size of a short line, so that there can be no entrance of septic matter, through this channel Of course the perineum is supported with two fingers in the mother's anus to assist the flexion in the occipito sacral, and right or left occipito iliac positions The tractions to bring the head down to the pelvic floor are sometimes very difficult of execution and very fatiguing to the accoucheur Here Pajot's method should be resorted to, or Tarnier's forceps used until the pelvic floor is reached, then should be laid aside and replaced by any ordinary forceps, Elliott's Simpson's and Hodgs' especially, which are, on account of their small pelvic curve, safeguards to the perineum

By observing the above precautions, the perineum will entirely escape laceration, and a man may have a large experience in delivery in such cases, without having to stitch a single perineum

DISCUSSION

DR. E W SAWYER, Chicago The subject introduced by the classical and very interesting paper, just read, has a peculiar interest to me, as unfortunately I have been obliged to study it in its various details all the years of my practice, thirteen in number The time permitted me to discuss this paper is too short to admit criticism on some points which have been advanced I will briefly state what my experience has been in this direction as I think it is one of the most important complications that presents itself to the general practitioner, because it occurs with such frequency Many of the living writers and teachers state that the occiput presents in the right of the woman's pelvis once in a hundred times The statistics of Naegelé show that there is a vertex presentation once in five times My own experience confirms this observation with great exactitude In 103 cases of vertex presentation the occiput presented posteriorly in 38 This series I had the honor to classify and discuss before the American Gynecological Society in this city some three years ago Since that time 16 additional vertex presentations have occurred in my practice, making in all 54 cases in which the occiput was in the posterior part of the pelvis These cases have taught me some important lessons In the last series of 16 cases,, 7 were in the practice of other physicians in this city who will confirm what I will say I would like to ask Dr Boisliniere, when he states that the occiput usually turns forward by the effort of nature, how many times he has thus seen it rotate forward?

DR BOISLINIERE Perhaps in two thirds of the instances

DR SAWYER I will state to you in all sincerity that I am not a reckless meddler in obstetrics, but I have never seen the occiput turn forward in any of my cases I believe there is nothing in the pelvis to stimulate its turning forward A century and a half ago Smellie, than whom no more accurate observer has since appeared, said that the occiput was never known to turn forward When the forehead occupies the anterior half of the woman's pelvis it should always be turned, that is the secret of success, that is the secret of saving these children and preventing the extreme mutilation of the mother The ideas which I advanced in my paper before the learned Gynecological Society were criticised with some severity Prof Richardson, of Harvard, and Prof Reamy, of Cincinnati, expressing the belief that it was meddlesome to turn it forward, that the position occurred less frequently and that we could patiently wait until it did turn forward Being impressed with these criticisms I left that meeting determined that at the first occipito posterior position I had, I would wait In December following the reading of that paper a case presented itself to me in a healthy young English woman, a primapara, whose waters broke prematurely, as they are very likely to do I sat by that woman's side, the fetal pulsations assuring me of the integrity of the child, twenty four hours No evidence of an attempt on the part of nature to turn that occiput forward Still I determined to wait longer, and at the end of thirty hours the occiput popped out and mutilated the perineum to a shocking degree I may say in addition that the repair of this perineum was followed by a second pregnancy and I delivered the woman of a child without injury to the repair Following the maxim of Smellie, I believe there is but one way You may sit for hours waiting and nature will never rotate it The very obliquity of the planes the gentleman has described will prevent the occiput from turning forward I would like to speak of the causes of these presentations of the occiput, I think they are due less to extension of the head, as stated by Lusk One interesting fact in my own cases is that over two-thirds of the number were primaparæ, and the great frequency of this presentation in this class has led me to inquire into the difference between the multipara and the primapara and I think it is due entirely to the fact that the abdominal parietes are less elastic in the primapara, and in obedience to that law the dorsal surface of the fetus is placed into that hollow at the side of the woman's spine and is thus placed more obliquely I believe it is the inelasticity that turns the occiput backwards Smellie relates graphically and with great sorrow how he delivered a woman under these circumstances He waited until the woman was exhausted when he took a blunt hook and put it under the chin of the child He says, "I

took a hint from that case which I put into practice in my next," and he tells how he applied the forceps to the sides of the head and forced the head to rotate forward, and the result to the mother was very satisfactory In my own practice the same rotation is invariably carried out but not with the forceps It is not difficult, as has been intimated by the reader, to rotate the head forward, it is one of the easiest and most satisfactory things to do in obstetrics You have only to carry etherization to a satisfactory degree then introduce the entire hand and seize the sphere which presents in the palm of your hand, and nine times out of ten, even with fingers as short as mine, you can touch the forward shoulder and with the finger turn the body with the utmost facility Not once have I failed, and gentlemen here can attest to more than one case in which they have sat all night waiting for nature to turn the occiput, I have been called, the woman etherized and in fifteen minutes delivered of a living child Assistance can be rendered by the unoccupied hand by palpation over the woman's belly The satisfaction I have had in relieving gentlemen who have sat all night waiting for these cases has been greater than that I have experienced in any other department of practice

DR BOISLINIERE, St Louis, Mo The recognized position of the occiput is backward Naegele teaches that the frequency of the position of the occiput is first to the left anteriorly and last in frequency to the right posteriorly He says that out of 100 cases of vertex presentation, the occiput was 70 times to the left anteriorly and 27 times to the right posteriorly, and there is no better authority in obstetrics on this matter than Naegelé The fact of the occiput having been found often to the right posteriorly and having rotated to the right anteriorly, the Doctor denies the possibility of, because probably he has met with the difficulties I mentioned, in his cases Either the sacrum was very flat, the spine of the ischium projected so much into the cavity of the pelvis as to prevent the forward rotation The spines of the ischium have a great deal to with the rotation of the occiput forward I appreciate the Doctor's remarks very much, but in his cases I believe the spine of the ischium has prevented the anterior rotation of the occiput, or there has been a very flat sacrum, or a very large sacrum, else one of the factors have been wanting, there were not enough uterine contractions and probably the floor of the pelvis had been ruptured by previous labor or was very much relaxed I have attended between 8000 and 9000 cases of labor and have frequently seen the occiput face posteriorly to the right and rotate to the right anteriorly, but it requires a strong pelvic floor and no opposition from the spine of the ischium and labor favored greatly by the efforts of nature Of course the rotation is very painful In all my practice I have never ruptured a perineum I think the Doctor's method is allowable only in cases of multiparæ I do not think you can use the whole hand with a primapara, where the perineum and vagina are very small, unless you first perform episiotomy The Doctor's method is excellent when the woman has had children, the perineum is large and the child small

DELIRIUM GRAVE

Read in the Section on Practice of Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association

BY E C SPITZKA, M D,
OF NEW YORK CITY

Synonyms —Delirium Acutum, Mania gravis, Typhomania, Bell's Disease, Délire aigu[1], Manie grave, Phrenitis

The disorder I am about to consider, owes its importance not so much to its frequency as to the fact that it furnishes opportunities for grave yet excusable errors in diagnosis It may fall to the lot of the general practitioner to see but a single case in a life time But that very single occasion will prove a memorable one On the one hand his diagnosis will oscillate between typhoid fever, meningitis, sun stroke and hydrophobia On the other he may be misled, through the occurrence of lucid intervals, to predict the recovery of a patient, who is in reality suffering from one of the most malignant and fatal affections of the nervous system to which mankind is liable

The nomenclature of acute fatal delirium reflects this great uncertainty The ancients spoke of it as *Phrenitis*, a curious term which still finds a place in certain vital statistics Abercrombie described an "inflammatory paralysis of the brain"—a term which is quite as good a one for a certain group of cases as any used According to Bell, alienists who occasionally saw cases of this disorder, classed it as a very acute and intense form of maniacal delirium Clouston, as recently as two years ago, illustrated this opinion of Bell by describing a typical case as one of acute mania in his "Lectures on Mental Diseases" The former an American writer, struck by the remarkable resemblance of the symptoms to those of adynamic typhoid delirium, devised the excellent name, *Typhomania* The French gave it the non committal designation, "acute delirium," which, owing to its ambiguity, I have proposed to change to "grave delirium"

The writers of the last decade assumed that grave delirium was a clinical entity Schule, Krafft Ebing and I have assigned it a special place in psychiatrical classification Serious objections exist to placing all cases manifesting such delirium in the same category Furstner, Mendel and others have shown that cases having the most different origin, may resemble each other in the final stage, and they demonstrate that Jehn and Schule were thus misled The experience of physicians limited to cases received in asylums does not cover all phases of the disorders in dispute Many are received in general hospitals in a moribund condition, or soon die there, others are treated at home, on the theory of isolation or essential fever Exceptional opportunities enjoyed by me during the past eleven years, and obtained in part through the courtesy of my lamented friends, T A McBride and Wm A Hardy, enabled me to review the subject in the light of altogether thirty one cases of real and spurious delirium of this order

[1] Brierre de Boismont, op cit

I shall first describe the typical form

The previous condition of most sufferers from grave delirium is usually poor General nutrition is impaired, and there is an obscure malaise, comprising ill defined nervous and slight gastric disturbances Sometimes the outbreak of the disease is preceded by from four to six weeks, by a matutinal headache This is described as a feeling of tension and often associated with vertigo The patient is irritable, light, sound and in some cases even odors annoy him Sleep is disturbed He finds it difficult to collect his thoughts, he feels conscious that he is morbidly emotional, but is unable to restrain this, and in a remarkably large proportion of cases there is a sense of some impending misfortune

The onset of the disorder may be so sudden and accompanied by so total a subversion of the mental and physical powers as to suggest the fulminating type of epidemic cerebro spinal meningitis, or the action of a violent nerve poison The patient while walking on the street, suddenly totters and if he do not fall stumbles about aimlessly like a drunken person At other times, while taking refuge from the impending misfortune dreaded by him, the sufferer breaks out in violent acts, which are, however, rather manifestations of anxiety than of aggressiveness He clutches at those about him, tearing their clothing or hair and then delirates about his enemies, refuses food because it contains poison, complains of crawling vermin has hallucinations of policemen, negroes, or of multitudinous images of a more frightful character, such as toads, snakes, bugs, goats and horses' heads, "with flaming eyes" Such visions cause him to pause in his delirious talk and to look in an alarmed or threatening manner at certain parts of the room In some cases the visions are of a pleasant nature, and the accompanying delirium may be of an ambitious, religious or erotic tinge Flaming spectra of angels, numerous husbands and countless lovers are seen, and in the midst of ecstatic contemplation, the patient starts, awakened by the voice of God or of a paramour, who delivers flattering missives in a voice of thunder or a glare of celestial light Sometimes the terrible and pleasant alternate in the history of the same case In that event corresponding changes in demeanor of a most dramatic character are noticed The attitude of a timid hunted victim gives way to theatrical gestures, and exclamations of terror to praying, singing and whistling In the erotic form, obscene gestures are indulged in, and the genitals are manipulated either automatically or with a definite purpose Rapid changes of this kind are particularly observed in females At one time such patients will dance and jump around laughing immoderately and vociferating, at another they will be found dissolved in tears, or try to escape from their imaginary foes with an air of intense anguish

A noteworthy feature is, that even with this violent onset, there are periods of relative lucidity and apparent health, in which the patient may recognize his delusions and hallucinations, perhaps try to explain them away, by admitting that he has been drinking too much, or may voluntarily consult a physician But in the latter event the uncontrollable nature of the disorder exhibited a sinister illustration in one of my cases The patient complained of something "funny" in his head, said that everything seemed confused and that there was a load on his chest But while dilating on the latter feature he suddenly exclaimed, "they want to burn me," "poison is in this atmosphere," "keep me in your office, doctor," "I am crazy, and they want to take me to an asylum" Then he passed into the wild delirium characteristic of the height of the disease

The development of the disorder takes place amidst increasing insomnia The flight of ideas becomes wilder, but more stupid True remissions no longer occur in the delirium, but there are spells of quietude due to exhaustion Indeed it is remarkable that with the unceasing raving and motor activity at this stage, fatal exhaustion does not close the history of the case thus early The patients roll around, kicking, grinding their heads against the wall, twirling rubbing or beating their hands so as to actually mangle them, and maintain the most singular and uncomfortable positions for hours and days Speech becomes more and more indistinct, and there is as kaleidoscopic confusion of syllables and words as of ideas

At the acme of the disease thus developed, everything about the patient indicates that he is suffering from something more than a mere mental disturbance Every symptom attests that he is the victim of a profound bodily disease The head is at first hot, the conjunctivæ injected, the expression is stupid and the face suffused and turgid Later on cyanosis often sets in The carotids may appear to throb violently, but in reality cardiac action is extremely feeble, the pulse being filiform, easily compressible and ranging from 110–160 It shows a striking parallelism with the temperature The latter is high, running from 101° to 104°, but in the stage of collapse, and those spurious remissions due to collapse, often becomes subnormal The pupils are in most cases dilated, myosis is occasionally observed, and while light reaction is commonly unimpaired, it is sluggish in a few cases The expression of the countenance is peculiar In some, particularly those who indulge in obstinate mutism the eyelids and lips are tightly closed, and every attempt to open them is firmly resisted Others keep their eyes fixed on a special point, such as the gas fixtures, making all the while a peculiar blowing motion with the mouth and cheeks, with more or less regularity and with no conscious purpose As dissolution advances, the features become drawn, giving an indescribably sad expression

The delirium which has given its name to the disease, is either wild or rambling It may continue in any of the channels indicated at the outset, being accordingly either aggressive, expansive or depressive As the disease progresses it becomes more and more monotonous and is often limited to one subject Soon this monotony extends to the mode and form of expression The faculty of expressing himself, even in broken sentences becomes lost, and the patient, after passing through a period of syllable

confusion, makes meaningless sounds which are endlessly repeated Still, even amidst this wreck of the mental mechanism, a predominant idea can be occasionally discovered In one of Brill's cases, the name of the girl's seducer, in another, one of my own, the occasion of a quarrel which had been the exciting cause of the disease, and in a third the name of the Deity, were repeated in an impressive manner until utterance failed Undoubtedly much of what is represented as insanity in romance, is based upon a picture of grave delirium, perverted by lay tradition

Indications of illusions and hallucinations are frequently observed One of my patients insisted on the removal of a pair of legs which he claimed were in his bed Another yelled that they were drowning him in something that smelled like benzine, a third picked off the "crabs" with which he imagined himself to be covered With this there is extreme motor agitation which ultimately becomes aggravated until a most unprecedented form of automatic violence is developed Cases are on record in which the patients literally converted themselves into one continuous bruise, others in which they picked, chafed or rubbed their matting and bedding into furze They may bore away at the sides of their room with their heads until the plaster is worn away, or break out in blind and purposeless motor delirium, kicking, striking and developing force that half a dozen skilled attendants may fail to restrain the sufferer Others will indulge in less aggressive acts These will stamp on the floor as if laying a Belgian pavement, continue making salaams for days, or rub a finger knuckle against their teeth until the bone is exposed, or the joint actually gnawed off In one case described by Sander the patient, a young girl, had torn her perineum and made great rents in her vulva These movements which occupy a position intermediate to the clonic spasm and automation, are variegated or interrupted by tonic spasms They result in strange bodily contortions, resembling, though not identical with, those found in tetanus The maintenance of such uncomfortable positions for days at a time indicates a profound degree of anæsthesia In some cases the hand is *main en griffe*, the nails being pressed so tightly into the palms as to cut the latter In a number of patients there is a tendency to bite, and this tendency is so strong that in default of foreign object one such patient bit off his tongue It is this class of patients who exhibit a terror of water, and undoubtedly many cases of so called dydrophobia were naught else than cases of grave delirium To the best of my knowledge it is the only genuine hydrophobia in human pathology In a few instances peculiar forms of disturbed sensation, in addition to the anæsthesia already referred to, are observed In the event of pruritus patients may scratch their entire bodily surface until it becomes eczematous In the majority there are suggillations due to surgical causes, and these, owing to the depressed vitality of the patients, look like the hypostatic marks of dead subjects To add to the corpse like appearance entailed by this terrible disease, the extremities become cyanotic and œdematous In addition, herpes, bullæ, pemphigus, pustules and phlegmonous inflammations have been noted

As regards the somatic functions, those of the stomach are most constantly disturbed There is always a pronounced oral *ptor* and frequently bilious vomiting The appetite is ordinarily impaired or entirely destroyed, and the patients will reject the food after it has been placed in their mouths and spit on that which is still in the dish Pulmonary œdema often occurs In no case that I have observed, nor in any one reported by others, were the catamenia suspended or even delayed In this respect there is a marked difference between grave delirium and the typical acute forms of insanity

Death usually takes place quite suddenly, sometimes while the patient is yelling, at other times in coma, and is then preceded by *subsultus tendinum* In those cases which were carefully observed in the moribund period the symptoms indicated exhaustion of the oblongata Intermission of the pulse, hiccough, dysarthria and difficult deglutition are then noted The hydrophobia previously present may give way to thirst, though the patient be unable to swallow

It is a surprising fact that in the midst of the very acme of a disease manifesting the severest lesions of consciousness, those para lucid intervals should seem, which I have already commented on, as inexplicable features of the initial phase Even here the wandering and delirious attention may be fixed, the patient brought to recognize that he is ill, deranged, in a hospital, and that his *interlocutor* is a physician Yet, cases are reported in which such an interval lasted four days and the temperature went down But the physician must not be misled into giving definite assurance of recovery In a few hours the scene changes, and the march to the fatal termination is resumed Death may even take place in the very midst of a lucid interval, and no more touching circumstance can be experienced in medicine than to witness the mother of a family, who has passed through the mental hurricane of acute delirium first reduced to a level lower than that of the brute, to return to nearly full consciousness a few hours before death, cry over the escapades, she infers rather than remembers, having been guilty of sending for her children to take leave of them, and apologizes for the trouble given the nurses, to whom she makes a few appropriate presents If any fact in the history of grave delirium convinces me that it is not a form of ordinary insanity, but rather a somatic condition of which the delirium is a symptom, it is this very one

The causes of grave delirium may be summed up as consisting in an inherited or acquired predisposition, to which some exciting cause, such as will deeply affect the emotional faculties, or otherwise vitiate the nutrition of the nerve elements and determine congestive hyperæmia, is superadded

I have tabulated 11 of my cases in which the history was nearly perfect, and 19 of which good histories here furnished by other writers, making 30 cases in all The following tables accordingly show the influences of predisposing and exciting causes

TABLE SHOWING FAMILY HISTORY.

	Males	Females	Total
Insanity in direct ancestry		4	4
Insanity in uncles aunts, sisters or brothers	2	10	12
Normal family history	2	6	8
Not stated	1	5	6
Total	5	25	30

Of 20 known 16 had heredity

TABLE SHOWING INDIVIDUAL HISTORY.

	Males	Females	Total
History of previous attack of insanity		7	7
History of feeb'emindedness	1	2	3
History of ugly excentric or excited temper	2	1	3
History of alcoholism	1	1	2
No abnormal features		5	5
Not stated	1	9	10
Total	5	25	30

Of 20 not known 17 had acquired disposition

TABLE SHOWING EXCITING CAUSE.

	Males	Females	Total
Angry excitement	1	5	6
Fright and angry excitement		1	1
Religious excitement		1	1
Seduction		2	2
Depressing emotions	1	2	2
Overstrain	1		1
Alcoholic excess		1	1
Insolation alone		2	2
Insolation and worry		1	1
Not stated	2	10	13
Total	5	25	30

Of 29 known 13 had emotional causes

Regarding the age of these patients, which is stated in the case of 27, I find the youngest, a female, to have been 18 at the time of her death (Fron muller), and the oldest 50 (Clouston) Four are 30, three 34 two each, 37, 28, 27 and 26 The largest number, eighteen out of twenty six, were be tween the 26th and 37th years inclusive The av erage age was $34\frac{5}{6}$ years

It is noteworthy that only one sixth of the cases were of males

As regards the duration, in twelve cases where it was accurately known, it was nearly fifteen days, dat ing from the outbreak, the longest being nineteen, and the shortest six days Schule speaks of cases lasting but a single day, but he confounds so many different conditions under the head of acute delirium that, in the absence of confirmatory experience, I do not feel inclined to attach much weight to this statement

As to the prognosis, it may be regarded as almost invariably unfavorable Very few indeed recover, and then they pass through an intermediate period, of which dementia, and what I term focal amnesia, are the characteristic features With one exception, the recoveries reported were of persons in whose his- tory alcoholism or hysteria were prominent factors That one exception occurred in this country and was reported by Dr Harriet Brooke assistant physician at the insane department of the Pennsylvania Hospi tal As it is the only case in which the symptoms were well marked, characteristic, and in which the mor bid condition reached a high degree, that recovered, I will make the only reference to therapeusis which this paper is to contain, in connection therewith Morphine, which is of excellent effect in analogous conditions, is so utterly without influence on acute delirium, that what would, under ordinary circum stances, be toxic doses, can be given without even affecting the diameter of the pupil The only pro cedures that have any useful influence are those em ployed to combat the threatening collapse Hypo- dermics of ether have been used by me with excellent effect, and, as in congestive paretic dementia, ergotin exerts a beneficial influence In Dr Brooke's case both were given, the latter in combination with dig italis, a dose of croton oil administered, a large mus- tard plaster applied over the pericardium, and as soon as the oil operated, reaction from what threatened to prove a fatal collapse was established Of course, a tonic and nutritious diet are necessary adjuvants to such a plan of treatment But it is usually rendered impossible by the patient's refusal to eat, and if he eat, by the low state of his digestive and assimilative functions

There is one condition which is most easily con- founded with grave delirium, and that is the so called nervous or ataxic form of typhus This disorder is characterized by delirium, somnolence, stupor, and muscular tremor of an excessive character The presence of petechiæ, albuminuria, and the great cardiac enfeeblement increase the resemblance If we bear in mind that this form of typhus is most apt to occur in those cases in which depressing causes have acted on the nervous system, we will under- stand how even the etiological history of the case may mislead the diagnostician A characteristic eruption may be absent, the temperature may fail to furnish us with a reliable guide In these events, the presence of an epidemic, the initial chill, great thirst and the predominating muttering character of the de- lirium, are our only means of establishing the exist- ence of essential fever

Analogous conditions are observed in typhoid fever Exceptionally cases occur in which there is an initial delirium of such character and severity that the sufferers are sent to the insane asylum under the mistaken view that they are suffering from a strictly mental disorder As in grave delirium, paroxysms of screaming and violence may occur There are also sudden changes, the patient who at one moment attempts to jump out of the window, the girl who calls for a baby, or begs to be taken home, may rapidly subside into muttering delirium, coma and death Lucid moments are equally noted The exact and collateral evidences of typhoid are, however, less variable than those of typhus, and a diagnosis by ex- clusion is less difficult

There is a disorder, extremely rare, it would seem, which is termed acute grave hysteria, and which I should be sorely puzzled to differentiate from grave delirium Such cases, carefully observed during life, and analyzed post-mortem, are reported by Meyer and Fronmuller I have myself seen two, in which the hysterical character was most marked, and the temperature rose nearly to 103° In one of these there was a fatal issue The girl, depressed by moral

influences, exhibited spasms of face and eyes, lay speechless, refused food at times, and thus continued for nearly two weeks Then she suddenly developed restlessness, threw herself around in a peculiar way so as to lie across the bed, had crying and laughing spells, tremors of the extremities, aphasia, mutism and total anæsthesia There was mydriasis Consciousness, which was impaired as a general thing, was fairly clear at intervals. In the fifth week of her illness, while in a crying and laughing spell, she suddenly expired Of course, the predominance of motor symptoms at the outset, and the crying and laughing spells, spoke in favor of a hysterical disorder Those who saw the case with me had already given a favorable prognosis I diagnosticated grave delirium and gave an unfavorable prognosis My chief ground was the high temperature But I have since learned that a temperature of 102 5° is occasionally reached in the severer form of seizures occurring in the course of benign hysteria

In a number of cases a series of symptoms, not unlike acute delirium, has been demonstrated to have resulted from multiple infection of the brain due to ulcerative endocarditis

A few cases have also been described in which the results of a blow on the head, in a chronic alcoholist, during the prevalence of an epidemic of typhoid fever, and an ordinary suppurative meningitis, breaking out from some cause not distinctly traced in a person who had received a blow a long time before, accurately imitated the course of acute grave delirium If all these considerations did not prove that this symptom group was merely the terminal phase of a number of affections having this much in common, that the brain is alike overwhelmed in all by some severe and multilocular morbific agent, the anatomical evidence would seem to establish this proposition beyond a peradventure Cysticerci, when scattered in large numbers through the brain, have produced motor and mental symptoms not unlike those related Extremely acute cases of paretic dementia, which is a multilocular schirro encephalitis with vaso motor episodes, resemble it so closely as to have been confounded with grave delirium by Jehn and Baillarger Finally, I have observed a case in which I was able to demonstrate—crudely, it is true, for the methods of that day were such—that a case of delirious mania with paralytic symptoms was due to the presence of miliary foci, containing a capillary as a centre, surrounded by disintegrated brain detritus, and this in turn by a zone of invasion of micrococci Furstner found that the blood of those who suffer from that form which leads patients to asylums presents a peculiar consistency When removed from the finger during life, it is found to be of a remarkably dark color On microscopic examination numerous bodies presenting the character of detritus are found Contrary to what is the rule with dark blood, its fibrin coagulates rapidly and *en masse* He also found a peculiar condition of the muscles, these are brownish and exhibit exquisite amyloid degeneration, a change which, as is well known, occurs also in typhus, variola, pneumonia, puerperal fever, epidemic meningitis, and traumatic or rheumatic muscle disease This author does not find noteworthy organic brain changes, but in just such cases as those described by him, but lasting a little longer, Clouston describes a deposit of new material all *through the gray matter* Futterer found fifteen grayish yellow foci, visible to the eye located at the junction of the gray and white matter In a beautiful case of this kind I found hyaline and fibrinous exudation throughout the same districts, ten years before Futterer's paper was published Like him, I had regarded them as the result of thrombic stasis I may add that attempts to cultivate the bacilli found in the blood in this disease, by Briand and Marcel, failed

On reviewing the entire evidence relative to grave delirium in the narrowest sense of the word, we find the following facts prominently established

1 It attacks persons whose hereditary tendency involves what may be biologically regarded as a chemical, that is a nutritive instability of the nerve elements

2 The exciting causes are either functional abuses or external influences of a kind which would aggravate such instability, and overburden the metabolic capacity of brain tissue

3 The blood and muscles exhibit pathological conditions closely resembling, in the latter case, those found in zymotic disease

4 All we have to assume is that, in consequence of the defective chemistry of an invalid brain, and its inability to meet the emergency of the exciting cause, some chemical body is formed which is at once toxic to the new elements, and changes the constitution of other important structures *In other* words, grave delirium is to be regarded as a self intoxication analogous to diabetic coma

Whether the toxic agent be a ptomaine, or something analogous to the chemical body which Meynert, in a beautiful theoretical exposition, suspected the existence of in epileptic coma, comparing it to the cyanides, I am unable to say The structural changes in the brain are altogether secondary, they may aptly be compared to those resulting from alcoholic excesses An alcoholic excess may prove fatal, but no structural changes result from a single such excess A series of excesses extending over a long period of time may, however, produce degenerative and vascular lesions Similarly, the intense poison of grave delirium may prove rapidly fatal, and no characteristic lesion changes be found after death, while in cases of longer duration, secondary results of hyperæmia and sequential stasis, modified by the peculiar state of the blood itself, are left to attest the malignant influence of the mysterious poison to which this terrible malady must be attributed

---

[A full account of the morbid anatomy and pathological theory of this disease is given by the writer in the *Transactions of the American Neurological Association* for the current year]

REMOVAL OF NECROSED BONE BY IRRIGATIONS WITH WEAK HYDROCHLORIC ACID

Read in the Section on Surgery at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY EDMUND ANDREWS, M D , L L.D ,

PROFESSOR OF CLINICAL SURGERY IN CHICAGO MEDICAL COLLEGE SURGEON TO THE MERCY HOSPITAL ETC

In almost all cases of necrosis the dead bone can be removed without operation by the simple process of daily irrigation with diluted hydrochloric acid This is especially important in spinal necrosis and caries, but is also applicable to necrosis in other parts of the body

Nearly all our authors are silent on this subject, for though Dupuytren and other older surgeons have spoken of brushing the cavity with strong sulphuric acid, they contemplated merely a caustic action to change the condition of the diseased living parts, and not the dissolving out of the sequestrum Others however, have proposed the solvent plan, but without gaining a serious hearing in surgical literature Billroth, of Vienna, briefly alludes to the subject, but scouts the whole idea in the following strong, but ill considered language "Chemical solution of the sequestrum is not to be thought of If you were daily to pour muriatic acid into the fistulous opening, it would affect the newly formed osseous tissue as much or more than it would the sequestrum, which would be very unfortunate, as it must replace the latter Hence, the mechanical removal of the sequestrum is the only thing left "

In opposition to this high authority, I wish to state as the result of actual experiments that, by a little ingenuity in the management of the irrigation, most sequestra can be dissolved out, and if the solution be properly prepared it does not affect the living bone, nor act upon the soft parts, except as a good antiseptic, neither does it cause any pain In fact, by the addition of cocaine and morphine, it can be made anodyne

So far as my investigations have yet gone, I find no solvent equal to a weak solution of hydrochloric acid Sulphuric acid seems to limit its own action by precipitating the insoluble calcium sulphate in the Haversian canals, and blocking the further access of the acid Thin laminæ of bone will lie in a dilution of this acid for days with only a slight degree of decalcification Chromic acid is also inefficient, and stains the linen on which it happens to drip Nitric acid decalcifies the bone rapidly, but I have not yet finished the experiments for ascertaining its practical usefulness

The proper strength of the hydrochloric solution varies with the tolerance of the patient, the object being to keep it just below the painful point This will usually be found between one fourth and one-sixteenth of the strength of the officinal *acidum hydrochloricum dilutum*, although it can be employed somewhat stronger by the addition of cocaine and morphine The tolerance seems to be determined largely by the presence or absence of a good coat of granulations upon the living tissues Directly after an operation, the cut extremities of the nerves are painful on the application of any acid, however weak, but after a few days, when covered by granulations, they bear comparatively strong solutions without difficulty

The length of time required will vary with the strength of the solution, and the constancy of the irrigation The following experiments were made outside the body to get an idea of the rapidity of the action of the acid Fragments of actual sequestra which had been removed by operation were placed in bottles of acid of various strengths, and the time required for complete decalcification noted

TABLE SHOWING THE TIME REQUIRED FOR DECALCIFYING SEQUESTRA IN WEAK HYDROCHLORIC ACID SOLUTIONS OUTSIDE THE BODY

Experiment	Strength of Solution		Dimensions of Sequestra	Time required for Decalcification
1	1 16	the strength of officinal dilute hydrochl acid	4½ cm by 1 cm by 3 mm	142 hours
2	1 10	do do	3¼ cm by 14 mm by 4 mm very hard seq from tibia	120 "
3	1 10	do do	4¼ cm by 28 mm by 20 mm Very spongy tuberculous trochanter	24 '
4	1/8	do do	9 cm by 32 mm by 5 mm	117
5	1 12	do do	38 mm by 9 mm by 4 mm	120 '
6	1/8	do do	2¼ cm very hard sequestr	128 '
7	1/8	do do	5¼ cm by 13 mm by 1 cm	102
8	1/6	do do	8 cm long whole thickness of shaft of femur, diam 2 cm	96 '
9	1/4	do do	32 mm by 13 mm by 3 mm	102 '
10	1/4	do do	64 mm by 38 mm	54 "
11	1/4	do do	Block of cancellated bone 16 mm diameter	78
12	1/4	do do	Sundry small splinters	54 '

Average time of solution, about 95 hours

These experiments show that old sequestra, which have lain long in putrid suppurating cavities, are not deprived of their gelatiniferous animal basis In every instance the decalcified animal matter remained in full form, but, lying enclosed in granulations inside the body, it is rapidly absorbed, exactly like the decalcified bone drainage tubes when left in position

The method of effecting the irrigation is important If one simply pours a little acid into the fistula, as Billroth evidently understood the plan to be, he will accomplish nothing It is necessary to irrigate the whole sequestrum either frequently or continuously If possible, one should have two openings, so situated that the fluid may run into one, and thence along the whole length of the sequestrum and out at the other When necessary, new openings must be made in suitable positions, and left pervious by drainage tubes The next step is to fill a half gallon fountain syringe with the acid solution, and, hanging it by the bedside, to let it run very slowly through the diseased channel If a "through and through" irrigation is not possible, we can often obtain the same result by taking a small flexible catheter, especially of the kind having a curve near the tip, and called by the French *sonde coudee* By a little careful management this can often be carried to the farthest corner of the cavity, and by attaching it to the fountain syringe it will deliver the fluid beyond the sequestrum, and make it flow over it on its return outside the catheter Whenever the se

questrum can be thoroughly irrigated, its decalcification is a matter of absolute certainty within a moderate number of days The hydrochloric solution is a perfect antiseptic of itself, and during its use no other is required

After the solution is completed there remains the gelatiniferous animal matter of the bone, which is identical with the material of decalcified bone drainage-tubes, and like them is rapidly absorbed in antisepticized cavities I have commenced to investigate the possibility of dissolving it out at once with pepsin, but have not finished that part of the subject

Billroth raises the objection that the acid will dissolve the living bone as rapidly as the dead, or even more so So plain a point as this of course cannot fail to rise in everyone's mind, but I am sure that great man spoke from mere theory, and not from observation or experience Whatever one might fear in this respect, I find as a matter of experience that the weak solutions which I have used do not decalcify living bone Apparently the granulations covering the living osseous tissue protect it from contact with the acid, except in spots denuded by ulceration, and even there the circulation of the alkaline blood in the Haversian canals, and the constant exudation of alkaline serum from all raw living surfaces, bone included, protect it from the action of such weak acid dilutions as I have hitherto used At any rate, it is a positive fact that the sequestra are dissolved, and the cavity heals, without any perceptible injury to the living bone

No 6 Sixteenth St , Chicago

THE INFLUENCE OF THE DURA MATER IN CAUSING PAIN, REFLEX AND OTHER PHENOMENA, WHEN INJURED OR DISEASED

Read before the Section of Practice of Medicine, Materia Medica and Physiology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY W B FLETCHER, M D,

SUPERINTENDENT OF THE INDIANA HOSPITAL FOR THE INSANE,

The dura mater, the mother membrane of the body according to the ancients, is a much neglected and most important organ, for organ it must be regarded in the human anatomy To the average student and general practitioner the dura is but a tough inelastic, fibrous membrane of unusual thickness, which plays the part of a scaffolding and support for the brain

A careful study of this part, however, shows that it is not only the superstructure upon and in which the brain is built, but that it is an internal periosteum to the skull—a complex channel for the great venous currents through which course, not only the venous blood from the brain, but much from outside the skull,—likewise a soft, serous cover for the membranes of the convolutions and sheath for the cranial nerves It has, furthermore, a small arterial supply, which is gathered from branches of both the external and internal carotids, but is most peculiar in being a most sensitive organ with a greater combination of sensory motor and vasa motor reflexes than any other part of the body The nerves of the dura come from the Casserian ganglion direct, and from the three great branches of the fifth pair With these are combined branches of the facial and a number of sympathetic ganglia relating it to the spinal cord

Van Helmont and others of his school regarded the dura mater as the seat of sensation Marshall Hall (*1841*) was the first to announce that its irritation caused reflex actions In 1872, Dr John C Dalton showed that convulsions or contractions followed irritation of the dura upon the same side These observations have been confirmed by a large number of experimentalists, more particularly by Duret, who injected iodine and other chemical stimulants between the cranium and the dura and produced fracture of the skull at various points

All these experiments were upon lower animals—presumably dogs That the same condition exists in an exaggerated degree when the dura in the human subject is either diseased or injured, is recognized by Duret and others This author, who has written most exhaustively upon the subject, intimates that so much confusion may arise between reflected sense and motion arising from irritation of the dura, as to puzzle the advocates of cerebral localization He says "Certain opponents (of cerebral localization) have adduced these facts to prove that the localized movements, which are determined by the application of the electrodes on the pretended motor centers of the cortex, were in reality due to irritation of these sensory conductors "

I herewith submit a sketch of a few cases which illustrate to some extent the function of the dura as an organ of sensation and reflected motor contractions, first premising my remarks by calling attention to the anatomical points of the scalp and cranium The scalp is not normally acutely sensitive, its cutaneous sensibility is less than other parts of the skin, notwithstanding its sensory nerves are from external branches of the fifth pair of nerves The skull cap, when examined shows many openings, through which emissary veins pass from without inward, as can be plainly seen upon the dura by the numerous spots where these veins have been broken in tearing the fresh calvarium from the brain, through these openings in the skull frequently, but perhaps in abnormal conditions the extremities of the dural branches pass, it is from this, we have occasionally those dreadfully sensitive tumors of the scalp, or the more dreadful tumors of the dura, which Abercrombie, Louis, Wenzel Brothers, Cruveilhier and others, describe as commencing in the dura and making their way through the skull, lifting the scalp and finally breaking into fungoid masses of the most disgusting and painful kind upon the surface These external dural nerves, if I may so name them, also account for the excessively sensitive spots which some persons have upon the scalp, when they must avoid the pressure of even a brush or comb, and arrange the hat for the particular spot I doubt

not that a careful examination in such cases would reveal a sensitive tubercle or clubbed extremity of a nerve

Case 1 M C was admitted to the Indiana Hospital for the Insane in March, 1882 He was irritable, homicidal and suicidal, suffered great pain in the head—at one time so excruciating that he ran at the window bars (an iron grating) with all his force, lacerating the scalp in many places During the war he had been cut along the center of the right parietal by an exploding shell, ploughing a groove into that bone, into this the scalp had healed into a firm adhesive cicatrix With the intention of trephining in this case, a triangular flap was made leaving the scar in the center It was not possible to dissect the scalp up from the old wound, but required a chisel to separate the dense aponeurosis, the old groove was likewise thoroughly scraped Finding no evidence of a fracture and that the direction of the flying fragment was not likely to have caused one on the inner table, further procedure was dispensed with The wound healed in a few days with the result better than could have been expected The pain was gone and the patient while not yet fully recovered, is comfortable, works out of doors in the garden or on the farm, is more social and is considered a "trusty" on the hospital grounds

Case 2 J N, some eight years ago was near a boiler when it exploded, was struck by a fragment on the right parietal near its junction with its fellow and the coronal suture After a period of unconsciousness, he recovered so far as to pursue his vocation, that of a farmer Two years ago he had constant pain in the right side, also several epileptic convulsions followed by slight facial paralysis of the left side, and nearly constant twitching of the right face, neck, arm and hand

In trephining this case, June 26, I found thickened and adherent dura, which was broken up with difficulty causing at the time increased muscular contractions, but when I had cut a slit through the greatly thickened membrane and explored the convolution beneath, even to passing a probe through the cortex of motor centers, no convulsive action was excited, there was an escape of perhaps two drachms of fluid, and more after the operation, but the patient remains to this date free from pain, convulsions or paralysis

In six other cases in which I have trephined in insanity from traumatic causes, a like result, varying in degree as the location varied, was noticed

It is my opinion from the foregoing observations upon the anatomical relations of the dura mater to the skull, that

First, It is frequently the seat of disease or irritation produced by pressure, causing nearly all intra cranial head aches and neuralgias

Second, That disease or injury of the dura through its relations with the vasa motor nerves largely commands the blood supply of the cerebral centers, thereby affecting psychical, motor and reflex functions

Third, That reflex contractions produced by irritation of the dura mater are usually upon the same side of the irritation, but when the irritation is great, symptoms may be manifest upon both sides

Fourth, Great inter cranial pain in the cerebral regions is not an index of disease of those hemispheres, but of the dura mater

---

THREE CASES OF SYMPATHETIC OPHTHALMITIS ARRESTED BY EARLY ENUCLEATION OF THE INJURED EYE

Read before the Chicago Medical Society, May 2, 1887

BY F C HOTZ, M D,
OF CHICAGO

A few years ago a writer in the *Archives of Opthalmology* (vol xi, p 209) asserted that it could be definitely settled "that the enucleation of the injured eye does not arrest or shorten the course of sympathetic inflammation" But we need only to begin to look into the literature or to ask the views of several oculists to convince ourselves that the greatest difference of opinion still exists in regard to the propriety of removing the injured eyeball after sympathetic inflammation has started in the other eye Mauthner, for instance, takes the ground that under these circumstances the operation is not only useless, but in certain forms of sympathetic inflammation positively harmful, while Wecker, on the contrary, declares these views are not borne out by clinical facts, and insists that the operation should be performed in the early stage of sympathetic ophthalmitis

When men entertain and express such opposite opinions on a question it certainly cannot be said to be definitely settled, on the contrary, it seems to be still open to a great deal of discussion, and to call for further clinical observations before a definite decision can be arrived at

But to discuss this subject understandingly, it is necessary that our arguments and the clinical facts to sustain them, rest upon the same platform, in other words, it is necessary that we understand each other in reference to what we regard as the early stage of sympathetic ophthalmitis For our views in regard to this malady have recently been undergoing a material transformation, and the term, "the early stage of sympathetic inflammation," may have a different meaning in observations based upon the old views from what it means in observations made under the latest theory

As long as the theory prevailed that the sympathetic inflammation was transmitted by reflex irritation through the ciliary nerves, we naturally looked for the first evidence of sympathetic disturbance in that part of the eyeball upon which the ciliary nerves exert their greatest influence Tenderness of the ciliary region and inflammatory disturbance of the iris were regarded as among the earliest symptoms of sympathetic affection, while cases in which the first evidence of sympathetic disturbance was discovered around the optic papilla, were considered and reported as occasional and rare exceptions But since Dr Arlt (*Archives of Opthalmology*, Vol V, 1876,) has shown the uncommon frequency of inflam

mation of the optic nerve in eyes which had been enucleated on account of sympathetic disturbance in the other eye, clinical observations have been rapidly accumulating to show that the optic nerve plays a very prominent part in the transmission of sympathetic inflammation In fact the evidence has become very strong already that the sympathetic inflammation is usually communicated directly through the optic nerves, and not by reflex action of the ciliary nerves This has been positively demonstrated by Professor Deutchmann (*Graefe's Archiv*, Vol 28, 29, 30 and 31,) in a series of interesting experiments on rabbits for the purpose of proving the infectious nature of the sympathetic opthalmitis He injected the spores of aspergillus fumigatus suspended in a solution of chloride of sodium into the vitreous, the infected eye developed the symptoms of irido choroiditis and the other eye showed, one week after the injection, a marked hyperæmia of the optic disc No further changes occurred, no actual inflammation ensued in the second eye, when one injection only was made in the first eye Deutschmann therefore concluded that the injected spores became encysted too quickly so that they did not incite an inflammation severe and lasting enough to be propagated to the other eye He therefore modified this experiment by repeating the injection four times in twenty-four days in intervals of six days The result was a destructive irido choroiditis in the infected eye, and the development of the following changes in the other eye appearing in the order here mentioned hyperæmia of the disc, papillo retinitis, acute choroiditis, and cloudiness of the vitreous

The sympathetic inflammation induced in these experiments manifested itself first at the optic disc, proceeded then to the retina and the choroid, and finally advanced to the anterior part of the uveal tract, (ciliary body and iris) In other words, that part of the eye which has formerly been regarded as the primary seat of the sympathetic inflammation, the anterior portion of the uveal tract was the last one involved And since we have begun, in all critical cases, giving occasion for apprehending the possibility of sympathetic trouble, to watch the healthy eye with the opthalmoscope instead of looking out for signs of iritis or cyclitis a great number of cases have already been recorded in which the first signs of sympathetic disturbance were noticed in and around the optic disc These clinical observations give additional weight to Deutschmann's experiments, inasmuch as they show that the sympathetic inflammation in the human eye seems to take the same course which he always saw it take in the rabbit's eyes

But if this is the usual course of sympathetic opthalmitis, if we accept the view that it begins at the optic nerve and ends in the iris, it is not difficult to understand why enucleation of the injured eye usually proves of no benefit when it is performed at the first signs of iritis or cyclitis, for it is then undertaken at a period, when the sympathetic inflammation has long passed its incipient stage, acquired such force and intensity that it will run its course independently of the inciting cause, and has inflicted so much destruction upon the interior tissues of the eye that little could be saved should we succeed in promptly arresting the disease

It is therefore obvious that the usually negative results of operations performed at this late period cannot be set up as an argument against the operation, and are not admissible as evidence in the discussion upon the question whether early enucleation can arrest the progress of sympathetic inflammation To settle this question we must take those cases only in which the enucleation was performed when the first signs of sympathetic trouble were discovered by the opthalmoscope A number of such cases are already on record, and the results show that the enucleation performed at this early period can arrest the progress of the sympathetic inflammation and rescue the second eye from destruction and blindness

But as the discussion on this very important question cannot yet be considered closed, I wish to add to the clinical observations already published the following three cases from my own practice

Case 1 —Fragment of steel in the fundus of the left eye, sympathetic optic neuritis of right eye, enucleation, recovery of R E On May 31, 1885, a small fragment from a steel hammer struck the left eye of a young farmer, the next day the eye was very painful, inflamed, and the right eye became very dim

On the 12th of June he arrived in Chicago, and I found the following *status praesens* V = fingers at six feet only, marked pericorneal injection, some pain around the eye, especially at night, in the corner opposite the lower border of the pupil a fine linear scar, only 1 5 millimeters long, and in the lower portion of the iris a small oblique rent, the edges of which appeared retracted and adherent to the lens The pupil was round and of ordinary size, but under the effect of atropine the upper portion only dilated, so that the pupil had the form of a ¾ moon The opthalmoscope disclosed considerable disturbance in the lens in the shape of numerous dark lines forming a cobweb like network in the posterior cortex and extending through the lower portion forward toward the perforation of the iris, (track of foreign body) This obscuration of the lens rendered a free inspection of the fundus impossible Still I could ascertain that the papilla was normal, but a short distance from the optic disc, at its temporal side, my eye caught a bright white reflex as though coming from a small coloboma of the choroid, and at the nasal border of this white patch a blackish substance was dimly visible The vitreous humor did not seem disturbed Right eye normal My diagnosis was that the minute fragment of steel had traveled through the lens and vitreous body, and cutting its way through the retina and choroid, lodged in the sclerotic And the subsequent developments seemed to confirm my diagnosis By keeping the patient perfectly quiet in a dark room and by the use of atropine, I succeeded within a few days in alleviating the ciliary pain and in removing all the inflammatory symptoms

June 18, all inflammation subsided, the track of the steel through the lens very plainly visible, but the obsscuration of the posterior cortex more con

tracted and limited to the area of the posterior pole, and consequently interfering less with the examination of the fundus The white reflex could plainly be seen to proceed from a small oblong patch of exposed sclerotic, located about two disc diameters from the temporal border of, and almost in a horizontal line with the papilla The upper angle of the coloboma of the choroid was occupied by a black body surrounded by hæmorrhagic effusion into the adjacent retina

June 27, extravasation entirely absorbed, form of the coloboma changed, being broader, almost square with obtuse or rounded corners Parallel with and close to the papillary edge of the coloboma was a longitudinal black streak, the lower end of which thickened to a triangular projection out into the vitreous, no change in papilla and other portions of fundus, V = fingers at eight feet

June 28, V much worse to day, lower inner field and central vision abolished Change was noticed last night after patient had been out riding in a buggy Papilla quite red and ill defined, extensive detachment of the retina, three distinct folds, one fold extending from the upper border of the papilla transversely toward the location of the foreign body, a second fold embracing the superior temporal section of the retina, and a third fold the inferior temporal section

July 3, optic disc much redder and swollen, veins greatly distended The retina re attached in most places, only two small short folds of detachment above the traumatic coloboma of the choroid, between this and the papilla numerous small fresh extravasations Right eye normal

July 12, the past two days the patient had been complaining of occasional obscurations of the sight of his right eye, when reading a few minutes it begins to ache and soon afterwards the sight is clouded V = $\frac{20}{20}$ —, but when he reads the test types down from No 200, he has to stop at No 30, optic disc greyish red and its nasal border swollen and indistinct

I expressed it as my opinion that this optic neuritis was undoubtedly the beginning of sympathetic inflammation, and that the left eye should be removed without delay This was done and the enucleated eyeball was put in Muller's fluid for future examination

The right eye began to improve at once after the operation, and on Aug 4, before the patient left the city, the fundus of this eye was found perfectly normal again, V = $\frac{20}{20}$+, and no difficulty in continuous reading

The later examination of the enucleated eye showed that the fragment of steel was suspended in the retina and choroid, and that the white patch I had taken for the exposed sclerotic was an inflammatory exudate around the foreign body

Case 2 —Extensive laceration of eyeball by a piece of glass, secondary subchoroideal hæmorrhage by a blow, incipient optic neuritis, enucleation recovery Sept 7, 1886, James P , a barkeeper, was brought to me Two hours previously he was engaged in opening a pop bottle, it exploded and a piece of the glass cut his left eye in a frightful manner The wound extended from the upper nasal border of the cornea in a curve downwards across the cornea, and beyond its lower border into the sclerotic In the lower portion of the wound vitreous and iris protruded, the pupil was irregular and dilated, lens already opaque After cocainizing the eye, I removed the prolapsed iris and vitreous, washed it thoroughly with corrosive sublimate (1 5000) and no splinters of glass being found, closed the wound by two fine silk sutures, and applied binocular bandage The wound healed up nicely and the eye recovered from this injury—as my note book under Nov 30 states—with a smooth scar to which the nasal portion of the iris was adherent, and with a shrunken cataract, good perception of light in every part of the field, and normal tension Right eye normal with perfect vision

Jan 11, 1887, he returned, two days previously he was accidently struck on this left eye The pain from the blow was so severe that he came very near fainting The eye is very red, exceedingly sensitive to the touch, very soft, (T–2), anterior chamber filled with blood Right eye still shows normal fundus, V = $\frac{20}{20}$ Under fomentations with warm water the pain in left eye subsided, but it rapidly diminished in size, and on the 16th, (seven days after the second accident,) the right eye exhibited the first signs of sympathetic irritation, intolerance of strong light, phosphenes, quivering of the air, and disability to read more than two lines, and the opthalmoscope showed a slight hyperæmia of the papilla

Jan 19, the symptoms in right eye more intensified, dull pain over the eye, papilla very red and its outlines hazy The patient now realizing the gravity of the affection, consented to the enucleation of the left eye which was done at once This eye showed a complete detachment of the retina with corresponding shrinkage of vitreous, and over the nasal side of the sclerotic an extensive detachment of the choroid by a recent blood clot The right eye was quickly relieved from the sympathetic disturbance and recovered its normal function

Case 3 —Laceration of left eye, neuro retinitis and diffuse choroiditis with cloudiness of the vitreous of right eye, enucleation, recovery J J , aged 27, painter, was admitted to the Eye and Ear Infirmary Nov 15, 1886 Six weeks ago he injured his left eye by falling from a scaffolding, the sight was totally destroyed at once The eye has been very painful ever since the injury, and one week ago the sight of the right eye began to get dim I found the left eye very red, soft, tender, reduced in size, and disfigured by a deep scar across the cornea extending at both sides far into the sclerotic (result of the laceration) Right eye was free from pain and redness, its pupil large and regular, but the vitreous so cloudy that fundus could not be inspected, vision reduced to perception of light

The following day the left eye was enucleated, its optic nerve was much inflamed, and its retina completely detached

Three days after the operation the right eye showed symptoms of iritis (pericorneal injection and a few

posterior synechiæ) which however, subsided very readily under the use of duboisine By the beginning of December the vitreous had cleared up, so that the fundus could be plainly seen with the opthalmoscope, it showed the papillla very red, swollen and indistinctly defined, large tracts of the retina opaque white and its veins large and tortuous Repeated opthalmoscopic examinations made during the next two weeks revealed nothing new, except that the neuro retinitls was subsiding, but on Dec 16, when I inspected the fundus again, I was surprised by finding that I could not see it as clearly as I could only two days previously This haziness was caused by numerous fine brown specks which had appeared and settled on the anterior capsule of the lens, they looked exactly like the deposits on the posterior surface of the cornea in iritis serosa, but there were no signs of iritis Deutschmann reported[1] a case in which with a similar condition of the fundus such deposits suddenly appeared on the posterior surface of the cornea without any signs of iritis He at once declared them to be the spores of the neuro organisms, which had incited the sympathetic micro retinitis and had been carried from the vitreous into the anterior chamber In order to prove the correctness of his view, he punctured the cornea under aseptic precautions, withdrew with an aseptic pipette the aqueous humor and transferred it into a culture fluid As the focal illumination found the cornea free from deposits after the puncture, they were evidently washed out with the aqueous humor After thirty-six hours the culture fluid exhibited the typical forms of the staphylococcus pyogenes albus, and a few drops of this fluid injected into the vitreous of a rabbit's eye developed a destructive chronic iridochoroiditis

As the sediment on the anterior capsule of the lens in our case appeared under the same conditions, it seems very plausible that it too consisted of micro organisms, and I now regret that I did not follow Deutschmann's example in performing the experiment

This sediment persisted one week, then the specks gradually decreased in size and number, and in two weeks no trace of them was left And on Jan 16, the last examination of the eye showed clear media, normal retina and papilla, H $\frac{1}{9}$ and V = $\frac{20}{40}$

THE MICROCOCCI OF WOUND INFECTION

BY HORATIO R BIGELOW, M D

OF WASHINGTON, D C

The issue of THE JOURNAL for April 9th contains a report of the proceedings of the Medical Society of the District of Columbia, meeting of February 16, 1887 The discussion of Dr Burnett's paper turned largely to a consideration of the low forms of life in suppuration and putrefaction It was intimated that our knowledge of these germs was extremely limited The question was asked, Is there a microbe of suppuration? As the whole subject is one of pre eminent interest and importance, and as the literature bearing upon it lies scattered through the medical journals of many countries, it may serve a useful purpose to put into tangible form some facts and theories directly related thereto

Dr F J Rosenbach (Wiesbaden, 1884 "Mikro organismen bei den Wundinfectionn krankheiten des Menschen"), writes that there can be no pus without a microorganism, that in all processes of inflammation, with the exception of that occasioned by turpentine, quicksilver and phoshorous, some form of germ is the exciting cause He finds four (4) cocci, in different suppurative conditions, which he cultivated and then tested upon rabbits They produced exactly the same form of inflammation as that from which they were originally taken These forms are the *Micrococcus pyogenes tenuis*, the *Staphylococcus pyogenes aureus* and *albus* and the *Streptococcus pyogenes* The *Micrococcus tenuis* is a mild form, producing local suppuration, with slight fever and no disposition to a phlegmonous condition The *Staphylococcus pyogenes* is found in phlegmonous pus (osteo-myelitis and furunculous inflammations) The *Streptococcus pyogenes*, the *Kettencoccus*[1] of pus formation, is perhaps (according to this author) identical with Pasteur's *microbe en chapelet* and Krause's Kettencoccus It never produces true erysipelas but stands midway between *Traubencoccus*[2] and *Erysipelcoccus* Rosenbach says that no specific bacteria exist in pyæmia, septicæmia and puerperal fever, that these obtain through the workings of the Ketten or Traubencoccus, or more probably through one of the three forms of Rosenbach's "saprogenic microorganisms "

De Bary (Vorlesungen uber Bacterien, Leipzig, 1887) says, that bacteria may be found in the pus of any wound To the diseases caused by bacteria contagia belong the various wound infections, inclusive of those of the puerperal state, and those connected with the formation of pus foci, abscesses of the skin and internal organs, of local abscesses of the skin, furuncles, ulcers, even to severe affections In these affections we find bacterial forms in the infected places in exceptional individual cases, and according to the present views the excellent results of Lister's antiseptic method, that is to say, asepsis and neutralization of excitors of decomposition, furnish indirect proof that they stand in causal relation as excitors of decomposition to the diseases This may happen in one of two ways 1 As a local process, giving rise to suppuration and abscess, or it may be carried by the blood from the local point of infection to distant organs 2 Or at the local point, it may give rise to a non organized poisonous substance, (a true ptomaine, or something equivalent to it, and this may also be carried along in the blood current The *Streptococcus erysipelatis* which Fehleisen (Die Aetiologie des Erysipelas, Berlin, 1883) first demonstrated, but whose presence had been theoretically assumed sometime before by Koch, v Recklinghausen, Lumkowski, Volkmann, Huter, Tillmanns and Orth, has now assumed its specific

[1]Kette, a chain
[2]Traube, a cluster

place in bacteriology, this also may be said of the *Streptococcus febris puerperalis*

The *Staphylococcus pyogenes aureus* plays the most important rôle in pus formation Biologically it has the characteristics of the micrococcus of osteo myelitis indeed it is so hard to distinguish any morphological difference that it is not improbable that they are identical forms, producing in one case severe inflammation, and in another patient a milder form

Passet (Untersuchungen uber die Aetiologie der eitrigen Phlegmone des Menschen, Berlin, 1885) describes a *Staphylococcus pyogenes citreus*, and Kilt (Deutsche Zeitschrift f Thiermed , xii 1) describes a coccus from 0 0002 0 0005 mm in size which he found in the milk of cows with lymphatic inflammation Friedlander (Die Mikrokokken der Pneumonie Fortschritte der Medicin, 1883, 1 Bd s 715) has fully written up the *micrococcus pneumoniæ croposæ* Koch (Die Aetiologie der Tuberkulose Berl klin Woch , 1882) has done an equally valuable service for the bacillus of tuberculosis Whether any pus exist at all without the co operation of some germ is a matter as yet *sub judice*, but one which is being faithfully worked out, and concerning which we are having many learned discussions The experiments which have been made with chemical substances, that produced inflammations, without pus formation, when bacterial influences were kept out, are now being subjected to much criticism, (see Passet) In every degenerative process of the human body, tending to suppurative or putrefactive change, which has been *studied*, certain germs have been discovered, and reasoning from analogy, with a just balancing of probabilities, I am inclined to believe that there can be no pus without its characteristic germ

Laudable pus is that process of change which is rendered harmless in proportion as it is kept free from the contamination of external air—I mean that it will not assume putrefactive and destructive form until its chemical nature has been so altered that the germ, characteristic of this change, can live in it and multiply I do not believe that the coccus of laudable pus can become a factor for evil or change its form, but rather that for some cause the inherent nature of the pus itself becomes changes, and thus becomes a fruitful field for the growth of a more destructive germ Or the germ may have inherent potentiality for evil, awaiting only the proper chemical change to render it active

It is safe to assume the worst at all events, and to guard against a possibility of untowardness was Listerism inaugurated Even when the germ has not been discovered there have been found vegetative changes of equal potency We know of no germ that will not succumb to bichloride of mercury or to the biniodide, and if time shall demonstrate that used in a diluted form that is germicidal they are free from danger to the patient, I cannot see how the first and chief features of the treatment inaugurated by Lister, are any the less worthy of support to day than they were when first made public I have seen a very large amount of surgery, abdominal and general, during my two years and a half in Europe, but I have seen no unhappy results from a lavish use of germicides, *au contraire*, the percentage of recoveries, after even the gravest operations, is wonderfully good Some two months or more ago, I saw Sanger, of Leipsic, do a Freund's operation, and the woman is alive and well to day The advocates of non Listerism seem to have more unfortunate results from the use of germicides than do all of the other surgeons who make use of them

Karlsbad, Germany, April 28, 1887

MEDICAL PROGRESS.

Iodoform Injections in Cystitis —Chandelux recommends an intra vesical injection of an ethereal solution of iodoform in some rebellious cases of cystitis He uses an almost saturated solution, or one containing 13 grams in each 100 grams of ether He had obtained very favorable results in painful cystitis of tubercular origin, and in other cases of long standing, in which urination took place as often as ninety six times in twenty four hours Chronic cystitis often causes a decided thickening of the bladder walls, and by their contraction the capacity diminishes greatly If we attempt to distend the cavity by a tepid injection of boracic acid solution very severe pains are soon produced, the bladder rebels and the liquid is forced out between the sound and the walls of the canal The bladder loses its power to bear a distension of its walls

In employing injections of iodoformed ether, the bladder having previously been emptied by the patient, the distension is seen to take place with a certain degree of ease According to Chandelux's opinion there is an exact balance established between the expansive force of the vapors of the ether and the power of tolerance in the bladder walls, and it is this which constitutes the great superiority of this over all other injections An evident proof of this distension is furnished by the vesicular tympanites, which is revealed by percussion over the pubes The capacity of the bladder can be thus shown as well as by the amount of liquid retained, to increase gradually from day to day The rôle played by the iodoform is considered only secondary, and the author says that it is all rapidly washed out by the urine and never deposited upon the walls as concretions, which might afterward become the origin of calculi The first injections are usually attended with considerable pain —*Lyon Medicale*, June 5, 1887

Pepsin in Chronic Tropical Diarrhœa —Mr George Harrison Young reports three cases of chronic diarrhœa which had proved rebellious to ordinary methods of treatment In each case the treatment was stopped, and the patient placed on a milk diet, a half pint being taken every three hours, and 5 grains of pepsin given four times daily The record of his cases seems to show that great benefit was derived from the use of pepsin Mr Young states that he has used pepsin in a considerable num-

ber of cases, and always with success He claims that this mode of treatment is especially applicable to to that form of diarrhœa in which the motions are large and frothy These cases are due to insufficient digestion and secondary fermentation of the food When this form of disease becomes established astringents are useless and even often injurious Pepsin at once checks the diarrhœa Only milk diet should be allowed, and the pepsin may be given with the milk In typhoid fever, the author claims that pepsin, by increasing digestion and assimilation of food, will thereby lessen the diarrhœa and intestinal irritation, and by so doing will diminish the severity of the disease It is also useful in dysentery occurring in debilitated subjects —*Indian Medical Gazette*, Dec , 1886

TREATMENT OF FURUNCULOSIS —According to DR PALASNE, of Champeaux, the use of the iodide of iron favors the resolution of furuncles, hastens maturation when they are already present, and even prevents their appearance It acts as a microbicide, being eliminated by the glands of the skin and destroying the pathogenic microbe of the affection He usually prescribes Blanchard's pills of the iodide of iron two to four a day (that is to say 10 20 centigrammes of the iodide of iron), and he continues their administration for at least eight days after the last furuncle has disappeared As the iodide of iron is a very unstable compound, we may have to recourse to the following process Take in a glass of water a teaspoonful of preparation No 1 Powdered sugar, 40 grammes, iodized alcohol, 40 drops (mix rapidly, and put into a well corked bottle) Then take immediately a packet of No 2 Iron by hydrogen, 8 centigrammes, sugar q s Without reflecting in any way upon the results published by Palasne, we desire to inform our readers that we have had no personal experience at all as regards the efficacy of this method The remedies which in our hands have been of the greatest value in cases of furunculosis have been 1°, internally, the sulphides, and agents directed towards the general condition of the body 2°, locally, care of the skin, lotions of camphorated alcohol and aqueous sublimate solutions, and finally, applications of red plaster or emplastrum de vigo —*Journ Cutan and Gen-Urin Dis*, August, 1887

SALICIN IN SCARLET FEVER —MR W P MFHARRY, of Belfast, says My experience has convinced me that the pure alkoloid (salicin itself) is by far the best form to administer the willow in this affection If given early, after a free purge, the disease will certainly be arrested, but if the tonsils have become much swollen and hard, or if the pus has formed, nothing will prove effectual, and the disease will run its course In scarlatina, especially in that form known as scarlatina anginosa, salicin is of great value In those cases of simple scarlatina in which the disease is prolonged by the throat complication, salicin immediately effects a cure I have treated during the last three years twenty seven or twenty eight of such cases, and in no instance has failure occurred I do not consider it necessary or prudent to administer it in every case of scarlatina as a routine treatment Salicylate of sodium should not be given, as poisonous symptoms set in when it is administered in large doses to young children I generally give to a child 4 or 5 years of age five grains of salicin every two hours until the temperature becomes normal, afterwards the same quantity three times daily for a few days to prevent a relapse —*British Medical Journal*, July 2, 1887

HYOSCIN IN PARALYSIS AGITANS PROFESSOR W ERB speaks most highly of the usefulness of hyoscin in this form of paralysis He has observed no positive cures obtained by its use, but marked palliation of the symptoms In one case after long use a kind of remission was observed The others were much helped For some hours the patients were able to move their limbs freely and felt much more comfortable The trembling was removed completely in some cases and in others almost so for several hours or for a quarter or half day The usual dose was 2 to 3 milligrams, these small doses often also caused sufficiently marked by effects to prevent their being increased The improvement in the general condition was so much greater than the discomfort of the side effects that the latter were not objected to by the patients The by effects usually noticed where the medicine acted with unusual power or was used in a larger dose than was readily borne were generally a feeling of weakness, drowsiness, heat about the face, dryness in the throat, some dizziness, uncertainty of vision and heaviness of speech —*Therapeutische Monatshefte*, July, 1887

ACTION OF ANTIPYRIN AND STRYCHNIA —M CHOUPPE has recently presented to the Société de Biologie the results of further observations on the joint action of these drugs The convulsions caused by antipyrin differ very much from those caused by strychnia, they are much less tetanic, are not excited by external causes, and affect much less the respiratory muscles, so that asphyxia does not threaten life If in an animal under the influence of antipyrin strychnia in more than a fatal dose be injected strychnia convulsions occur, but a new dose of antipyrin causes them to cease, and antipyrin convulsions, which may last many hours without causing the animal's death, replace them It seems, then, that the two drugs administered in convulsive doses produce an attenuation in the rapidity of the development of convulsive phenomena —*Semaine Médical*, July 20, 1887

ANTIPYRINE IN CHOREA —WOLLNER has been lead to prescribe this drug in chorea by reason of its influence on the nervous derangements incident to rheumatism In the case reported, the attack of chorea followed a sudden disappearance of rheumatic symptoms Sodium salicylate, potassium bromide, and propylamine having been tried in vain, antipyrine was ordered in does of fifteen grains three times a day, a cure was effected in twelve days —*N Y Medical Journal*, July 30, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order drawn to the order of the undersigned When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters

INDICATIONS FOR THE INDUCTION OF PREMATURE LABOR

A few weeks ago DR GEORGE T HARRISON read an admirable paper before the New York County Medical Association on the *Indications for the Induction of Premature Labor*, which is worthy of careful study In general terms it may be said that the object sought in this operation is to give a better prognosis in those cases in which the further continuance of pregnancy, or childbirth at term, involves great dangers to mother or child, or both, by artificial termination of pregnancy at a time when the fœtus is capable of living outside the uterus As the chief danger to the mother, in the performance of the operation, is not, as formerly supposed, the mechanical irritation of the uterus but septic infection, it may be affirmed that, if proper antiseptic precautions be observed, this danger is an avoidable one

The first and most important indication for the operation is furnished by pelvic deformity of a moderate degree Theoretically, this indication is clear enough, but in practice several difficulties may arise in its fulfilment *First*, our means for pelvic measurements are imperfect, and only enable us to approximate to correctness *Second*, the exact period of gestation may be very difficult to determine, in certain cases deviating somewhat from the normal Irregularities especially occur in cases of contracted pelvis, from the fact that the head is prevented from entering the pelvic cavity, and thus certain signs of pregnancy are modified But, having fixed the date of gestation as accurately as possible, we must next decide in what week of pregnancy the induction of artificial labor is indicated The earlier the labor is induced, so much the less danger of injuring the soft parts of the mother, and so much greater the chances that the child will be born alive, but, at the same time, the prospect of the child's continuing to live diminishes in proportion to its prematurity On the contrary, the later the labor is induced, the greater the danger to the mother and child, but the better the prognosis for the survival of the child if living The problem, then, is to choose such time when the child could be born without injury to itself or the mother To do this we must get an accurate idea of the sizes of the pelvis and the child's head

In the flat pelvis, the deformity most frequently met with, we have simply to ascertain the measurement of the conjugate diameter In the equally contracted pelvis the problem is much more intricate Here we must introduce the whole hand into the vagina, in order to form an idea of the pelvic cavity, and errors are difficult to avoid To determine the size of the child's head also presents many difficulties Schroeder showed by careful measurements that the head is larger from the twenty eighth to the fortieth week of gestation than was generally supposed to be the case But it must be remembered that the heads of immature children are much more compressible than those of children at term Other criteria which may serve as guides are the facts that large and powerful women, as a rule, give birth to large children, and that the weight of the child increases with the age of the mother and with the number of preceding births The transverse diameter of the heads of the children of young primiparous women is relatively small, while the contrary is true in multiparæ who are comparatively old The method proposed by Frankenhauser and Roth of determining the relation between the head of the fœtus and the pelvis of the mother, is worthy of trial This consists in passing the child's head into the pelvis and, by means of the fingers in the vagina, ascertaining if it be possible for the head to descend below the brim This examination should be repeated every eight days, and operative interference should be resorted to only when the descent of the head below the brim seems no longer possible

As to the degree of pelvic contraction which justifies a resort to the induction of premature labor, Dr Harrison believes that in the simple flat pelvis a conjugate diameter of 7 5 cm , or 7 cm in very exceptional cases, should be the extreme limit In the equally contracted pelvis, when the shortest diameter is at least 8 cm , it may be said that the operation is justifiable As a rule, the thirty sixth week of preg-

nancy is to be selected, and only exceptionally should the term of gestation be anticipated by operating in the thirty fourth week

An indication for inducing premature labor is also given by certain severe diseases which endanger the mother's life and are amenable to no other treatment, while, on the other hand, either a cessation or an amelioration of the symptoms may be expected with the termination of pregnancy Among such affections is uncontrollable vomiting appearing late in pregnancy Occasionally it is so severe that operative interference is imperatively demanded Another disease which may indicate the operation is nephritis, though a distinction must be made between cases in which the anatomical and functional renal disturbances are evoked by the pregnancy, and those in which the disease is an interstitial or parenchymatous nephritis, which either existed prior to conception or was produced during the course of gestation As to the induction of premature labor to prevent eclampsia, Dr Harrison believes the indication clear and decided when the urine shows a constantly increasing quantity of albumin and fatty-degenerated cells, and when all other resources prove unavailing Again, excessive œdema and transudation into the serous cavities may demand the operation To diagnosticate between the two forms of nephritis referred to, *nephritis gravidarum* and *nephritis in gravitate*, is no easy task The clinical phenomena are so nearly alike that the previous history of the case and the course it took can alone decide as to which form is present in a given case It has been abundantly shown that in chronic nephritis in pregnant women there is a great tendency to abortion and premature labor, and not so much to attacks of eclampsia

A third indication for the induction of premature labor in the interest of the child, is met with in certain cases in which experience has shown that the children died at a certain date of gestation, when this time was not far removed from the end of pregnancy Some cases of *nephritis gravidarum* come under this category If syphilis be the cause of death of the fœtus, the artificial interruption of pregnancy Dr Harrison thinks is contra-indicated, for, according to Kassowitz, in latent syphilis of the father or mother the death of the fœtus takes place in each ensuing pregnancy somewhat later, so that in successive pregnancies these are first abortive fruits, then immature macerated, then prematurely born macerated, and finally mature, but diseased children, still later, mature healthy children On the other hand, we gain nothing by the artificial induction of pregnancy before the expected time of the death of the fœtus, for the child is already diseased, and may be considered as lost In cases, however, in which chlorosis or anæmia of the mother, or changes in the umbilical cord or placenta, have caused the death of the fœtus, the induction of premature labor before the critical period may be the means of securing a living child

It is rare that diseases of the heart or lungs give an indication for this operation, though they occasionally do Lastly, an indication for the induction of premature labor is furnished by those dangerous and incurable diseases of the mother which would probably cause death before the end of pregnancy, in order to avoid the Cæsarean section *post mortem* or *in articulo mortis*

DANGERS OF SALTS OF LIME

DR ARNOZAN, of Bordeaux, lately made a communication to the Medical Society of that city on the dangers of submitting children to the prolonged use of salts of lime He reported the case of a youth 14 years of age, who was affected with coxalgia, and who for six months took two table spoonfuls of a solution of hydrochloro phosphate of lime, a patent medicine, 20 grams of which contain one gram of the salt During this period the patient had, at a few days interval, three attacks of nephritic colic, characterized by vomiting and by very slight renal pains, the diagnosis of the nature of the colic would have been very difficult had it not been for the rejection ultimately of three small calculi during micturition The phosphatic medication was immediately suspended The nephritic colic did not return, and during three months there was no sign whatever of renal lithiasis The coxalgia appeared to be cured and the patient, although a little emaciated, did not present any lesion whatever of the internal organs

The most voluminous of the three calculi that were expelled was examined It was the size of a hemp seed, of a whitish grey color, the surface slightly rugose, and, weighed at the time 25 miligrams At the moment of rejection, the calculus was a great deal more voluminous Independent of a few traces of organic matter it was composed solely of the phosphate of lime This composition, the author remarked, is rather exceptional, adding that doubtless the phosphates are not rare in renal concretions, but they are not alone, and are generally found united with lithic acid or with lithic salts In the case under notice, on the contrary, the phosphate of lime was the only mineral element in the calculus

From an etiological point of view, says the author,

it is impossible not to incriminate the medication followed by the patient The composition of the calculus submitted to analysis, its formation in the youth who had no hereditary predisposition whatever to gravel and who absorbed considerable quantities of phosphates, the non reproduction of nephritic colic as soon as the medicine was discontinued all these circumstances put together do not appear to leave much room for doubt It must, however, be acknowledged that the immobilisation to which the patient was subjected might have favored the development of lithiasis, and no argument can be deduced from a single example against phosphatic medication, so excellent in a large number of cases Dr Arnazan suggests that the examination of the urine of patients submitted to the use of phosphates may furnish useful indications for the moment when it would be necessary to suspend momentarily, or altogether, the medication, and whether, particularly in immobilised patients, it would not be better to substitute the phosphates of soda and of potash for the phosphates of lime

THE "GOOD STANDING" OF MEDICAL COLLEGES — The brief comments we made on this subject in connection with a resolution recently adopted by the Illinois State Board of Health, have brought to our table a shower of questions Some of them are accompanied by names of members of the profession worthy of full attention, while others are anonymous and worthy of little notice Two of the more important of these questions, viz "Is the regulation of the practice of medicine by law desirable, and if so, who shall decide upon the qualifications and conditions required?" were answered directly and clearly in the editorial columns of THE JOURNAL for March 12, 1887, p 295–6, and for March 19, p 322–3 But for a more full consideration of the whole important subject our readers must wait until the more pressing work of the next thirty days has been accomplished Until then we will keep their questions on file

RAILWAY RATES TO THE CONGRESS, EXTENSION OF TIME —We would call the attention of the readers of THE JOURNAL living west of the Ohio River, who intend going to the meeing of the International Medical Congress next month, to the advertisement on advertising page 11 in last week's issue of THE JOURNAL, in regard to the facilities and equipment of the Baltimore & Ohio Railway

We also wish to state that inasmuch as the Trunk Line Traffic Association has allowed an extension for return tickets, used by those attending the Congress, until September 20, the Baltimore & Ohio Railway has also arranged to extend the time of all return tickets over their line to the same date, thus enabling those who wish to do so to visit New York, Boston, the seashore, and other points after the Congress adjourns This information is later than that under the department of "International Medical Congress," on a subsequent page

SOCIETY PROCEEDINGS

AMERICAN OTOLOGICAL ASSOCIATION

Twentieth Annual Meeting, held on Tuesday, July 19, 1887, at the Pequot House, New London, Conn

(*Concluded from page 184*)

A paper entitled, *Desquamative Inflammation of the Middle Ear, with remarks* by Dr O D Pomeroy, of New York, was read by title

DR E E HOLT, of Portland, Me, read a paper on

AN EFFICIENT POWDER BLOWER, WITH REMARKS ON THE USE OF POWDER IN THE TREATMENT OF DISEASES OF THE EAR

The powder blower consists of six or eight inches of small glass tubing to which is attached about fifteen inches of rubber tubing The glass tube is plunged into the powder until a sufficient amount is introduced into it The powder is gently drawn into the proximal end of the glass tube The distal extremity is then placed in the speculum and the powder blown into the ear By drawing the powder from the distal end before blowing it, it is carried *en masse* to the desired point and applied evenly to all parts The instrument can be used with great facility After trying various powders, boric acid has been found the most efficient in the largest number of cases One of the first cases in which the author had used this powder was one in which treatment for over two years had failed to cure a suppurative otitis media Upon the application of the powdered boric acid the discharge ceased and has not returned, a period of five years Cleanliness before using the powder is essential A comparison of cases of chronic suppurative otitis media treated with boric acid and with those treated without this agent, led to the conclusion, that while the discharge from the ear ceased much earlier when the powder is used, yet perforations in the drum head heal less frequently

DR SAMUEL THEOBALD, of Baltimore, exhibited a powder blower similar to that of Dr Holt, with the exception that the glass tube was substituted by a goose quill and that the rubber tube was furnished with a mouth piece consisting of a quill The powder is introduced into the quill and by shaking brought to the proximal extremity of the tube, the object being that it shall be thrown into the ear in the form of a cloud

DR WM W SLEIY, of Cincinnati, had never seen any benefit from blowing powders into the ear He had seen good results only when the powder was packed into the canal He now rarely used the powder in any way

DR B ALEXANDER RANDALL, of Philadelphia In treating a number of cases of purulent discharge which had continued from five to fifteen years and in which the discharge had been pretty continuous and fetid, I have cleansed the canal and used boric acid, at first blowing it in lightly and finally filling the canal pretty full without packing Within a few days the powder is dissolved and the discharge is usually diminished in quantity and the odor is lost

DR H KNAPP In acute cases of otorrhœa, I use boracic acid as antiseptic and cleansing powder The patient is directed to cleanse the ear with the syringe three times a day The powder is then introduced by means of a spoon until the canal is loosely filled If the powder becomes moist the patient is directed to syringe the ear and renew the application The majority of acute cases do not require any other treatment In chronic cases I remove any polypoid growth or any carious bone that may be present, and then use alcohol in fifty or sixty per cent strength, or absolute, with sulpho carbolate of zinc and change that with nitrate of silver I continue this treatment until the ear is dry and there is no discharge, and direct the patient to do nothing beyond using a light cotton plug to filter the air

DR C R AGNEW In using fluid applications in the treatment of these cases I have employed a procedure which may be new to some of the members After cleansing the ear in which I want to diffuse a fluid application as much as possible, I turn that ear uppermost and fill the external canal with the solution Then I insert the nozzle of the Politzer apparatus into the external canal and make pressure diffusing the liquid to all parts of the ear and making in appear in some cases in the pharynx This sometimes may be of value

DR SAMUEL THEOBALD I have never seen any direct harm follow the use of boracic acid In cases of suppuration with a small or moderate sized perforation, I have seen it dry up the discharge and leave the perforation larger than before its use In such cases, I prefer solutions In acute cases, my practice is to always use solutions Where the drum membrane is practically gone, with a granular condition of the mucous membrane, the use of boracic acid powder is indicated I have never found it necessary to pack the canal One puff of the powder blower fills the canal sufficiently full

DR H KNAPP In acute suppurative otitis which is certainly of bacterial origin, I use boric acid largely on account of its drying properties Suppuration, fermentation and decomposition do not take place where a part is kept dry As soon as the boric acid becomes moist I have it removed For acute cases I know nothing better than this method of treatment

DR EMIL GRUENING I should like to make a few remarks with reference to three cases which I have already mentioned In these cases I attributed the fatal result to the use of powder which was boracic acid The first case was that of a girl 19 years old who had otitis as a result of the use of the nasal douche She was advised to use powders In a few days she began to suffer with headache, dizziness and intense tenderness on one side of the head and slight puffiness in the region of the mastoid I saw the patient after she had become comatose I found the tympanic membrane bulging, it was injected, and there was a slight tit-like projection and in this there was an opening filled with powder The pus which formed in the middle ear escaped through the Eustachian tube I made an opening in the membrane and cleaned it out carefully and advised the family physician to open the mastoid He did so and found the mastoid cells filled with pus The patient recovered consciousness but died the next day from heart failure The second case was that of a lady 70 years of age who had otitis media with perforation A powder was applied by a general physician and a few hours later she began to suffer with intense headache Symptoms of meningitis appeared and I was called in I found a small opening in the membrane occluded with powder I made an opening, but the patient died of meningitis The third case was that of a child with long standing otitis media, and destruction of both membranes This is the only case in which the powder had been packed After the ears had been packed the child had repeated chills I was called in and removed the plugs which were hard concrete masses and were taken away with difficulty In spite of the removal of the powder the child died with all the symptoms of pyæmia

DR D B ST JOHN ROOSA I think that in a large percentage of cases acute inflammation of the middle ear is a self limited affection I try to secure cleanliness and then dry the parts I do not use the dryness as a means of destroying the germs or preventing them from acting, for I do not believe in the germ theory of disease I think that germs are the products and not the causes of disease I think that they retard recovery and therefore should be removed In a large proportion of the acute cases the only treatment required is irrigation with warm water pro re nata and drying afterwards I believe that the pus has a chemical quality apart from the presence of germs which renders it corrosive I therefore try to keep the parts as free from pus as possible

DR CHARLES H BURNETT, of Philadelphia, reported

AN EXAMINATION OF FIFTEEN DEAF MUTES BY MEANS OF J A MALONEY'S OTOPHONE

The cases examined were pupils in the Pennsylvania Institution for the Deaf and Dumb, Philadelphia, and were between the ages of 12 and 21 years The cases were divided into three classes 1, congenital cases, 2, those losing their hearing between the ages of 1 and 5 years, 3 cases of profound hardness of hearing, but who still hear a little and can talk—so-called semi mutes The method of pracedure was as follows five vowels were written and pointed out and the time of their repetition three

times in succession through the otophone by Mr Maloney The pupil was then told to indicate which vowel was spoken when Mr Maloney made another repetition, care being taken to mix about in the tests The words Philadelphia, Mississippi, Burlington, Missouri, boy, baby, papa, and mama, were also used as tests, as well as the consonants Hearing was excited in every instance, but fourteen of the fifteen cases gave ample evidence of hearing by their successful indications with the pointer as the different tests were repeated in their ears It was noted that the results were not as good with the acquired cases as in the so called congenital cases of deafness This may be due to the fact that the process productive of the acquired form is more violent, involving the internal ear, as in spotted fever, than in congenital cases which generally give evidence of being simply catarrhal in their origin and affect the middle ear but not the internal auditory organ In the case of semi mutes the results were especially satisfactory as they heard nearly everything said to them and returned intelligent answers to the questions In such cases both the remaining hearing and the articulation could in all probability be improved by the systematic employment of such an instrument as the otophone as a means of instruction, the best results being obtainable where the instruction is begun early in life

A paper with the same title, presented by Dr F B Loring, of Washington, in the absence of the author, was read by title

Drs H L Morse, of Boston, and B Alexander Randall, presented a series of *Photographic Illustrations of the Anatomy of the Human Ear*

Dr Samuel Sexton reported an

EXCISION OF THE OSSICLES OF THE DRUM OF THE EAR FOR CHRONIC PURULENT INFLAMMATION OF THE MIDDLE EAR TRACT

Since bringing this subject to the attention of the Society one year ago, the writer has continued the practice with satisfactory results, and presented some further observations based upon the records of nineteen operations Of these nineteen cases thirteen were females and six were males Seven cases were between 5 and 12 years of age, eight were between 13 and 20 years of age, and four were between 13 and 40 years of age The left ear was affected in eleven cases cases, the right ear in eight In two cases both ears were the seat of suppurative inflammation, and in one there had been a mastoid abscess In the majority of cases there had been a history of recurrent aural catarrh for a long time, attended with pain in the ear There was much deafness and distressing acoustic phenomena, as autophonia and the like The discharge was usually offensive The general health of most of the patients was fair In all cases the drum head was greatly impaired, the membrana vibrans being usually almost entirely gone, in most of the cases the membrana flaccida alone remained, perhaps with some portion of the membrana vibrans attached Where any of the latter remained it was liable to be found connected by bands to the inner wall of the tympanum Sometimes a sinus of greater or less size opened through these diseased structures into the attic The membrana flaccida, together with the membranous and ligamentous attachment of the ossicles generally held the latter in place even after the most extensive suppuration had long existed Under these circumstances drainage was extremely likely to be interfered with The manubrium and cicatricial structures depending from the auditory plate were frequently found adherent to the inner wall of the tympanum, while the attic and antrum were lined with much thickened mucous membrane Some portion of the middle ear tract was found to present more or less carious bony surface In some instances the ossicles themselves were carious or anchylosed In several of the cases the malleus handle was adherent to the inner wall of the drum In some only a necrosed stump remained In some the malleus and incus were adherent to each other The incus was less liable to caries The stapes cannot be so well examined as the other bones, since it is never removed In some of the cases the operation was not resorted to until months or years after ordinary methods of treatment had been unsuccessfully resorted to

Without going into all the details of the operation, the author said that experience had shown that it may be performed much more rapidly than was at first supposed The first operations required an hour, the later ones not more than fifteen minutes To the protracted operation he attributed more disagreeable symptoms, such as nausea, which had not been presented by the later cases The remaining fragments of the drum-head are everywhere detached from the tympanic ring with a slender trowel-shaped knife The malleus is then freed from its attachments, including the tensor tympani muscle, by one or more sweeps of the knife After all blood is removed the long process of the incus is separated from the stapes, if it be connected with that bone The malleus handle is separated from the inner wall of the canal, if it has been attached The malleus handle is seized with stout forceps as high as possible and gradually detached and brought away The removal of the incus is more difficult, since its long process is likely to be swept from view With a little patience, however, the bone may be soon found and its removal is then a simple matter When lying in the attic, the scraper may be of service in bringing it down In most instances he no longer divides the chorda tympani In some cases where the ossicles were very adherent, considerable force was necessary to detach them, and in one instance this was impossible After the operation the drum should be carefully dried with cotton, and ten drops of a four per cent solution of cocaine may be instilled This is usually unnecessary Usually very little or no reaction follows the operation until a little time after the menstrual period

In the nineteen cases both malleus and incus were removed in ten In one the body of the incus alone was removed In six cases the malleus only was excised When possible it is well to clear the drum of granulation tissue by treatment before the operation, since less hæmorrhage will then be encountered

The duration of treatment after the operation was, in five cases, one month, in two, two months, in one, six months, and of the other nine cases, three were unimproved, one failed to continue treatment, and five are yet under observation Nine cases progressed steadily to a complete cure, six were much improved, three were unimproved, and one failed to continue treatment Many of these were dispensary patients, under bad physical conditions A marked improvement in hearing occurred in nearly all cases In the cases noted as cured it increased 75 or 100 per cent, as far as testing with voice was concerned

This marked improvement in hearing was unexpected, and gave rise to the conjecture that we may recommend the operation for deafness alone in many cases where the drum is obstructed by the results of chronic purulent inflammation, although all discharge may have ceased

Reproduction of the drum head never took place Among the results of the operation may be mentioned the prevention of recurrent accumulations of purulent matter in the attic and antrum The general health was nearly always improved In two phthisical cases the cough was lessened in one and ceased in the other, while both gained much in weight In children the effect on health was most marked

The operation is performed with the patient upon the back and under ether narcosis The electric light is almost essential Magnifying lenses introduced into the speculum are of service The after-treatment consists in keeping down granulation tissue and aiding in the transformation of the mucous lining into a dermoid condition A meddlesome plan of treatment is undesirable Where a large secreting tract exists a cure is sometimes almost impracticable Alcohol has not been found useful in treating granulation tissue Salicylic acid and boric acid have done good in a few cases The peroxide of hydrogen has its use in certain cases The persistence of discharge after operation may be expected in catarrhal and run down subjects, especially where caries of the bone exists

EVENING SESSION

A case of Rapid and Almost Total Loss of Hearing in a Child 7 years of age, Inherited Syphilis Apparently the Cause, Marked Improvement following the use of Iodide of Potassium, by Dr A H Buck, of New York, was read by title

DR SAMUEL THEOBALD reported a case of

SYPHILITIC DISEASE OF THE LABYRINTH,

exhibiting remarkable variations in the degree of deafness The patient was a man about thirty four years of age, the subject of inherited syphilis In one ear the deafness was nearly complete, and in this ear there was but little variation In the other ear frequent and sudden relapses occurred, after the hearing on several occasions had been brought up almost to the normal standard Within twenty-four hours the hearing would fall from the ability to distinguish words in a whisper at twenty inches, to a degree of deafness which would require the same words to be spoken in a loud voice Iodide of potassium was given with but little effect, but decided benefit resulted from the administration of bichloride of mercury in combination with muriate of ammonia

EXECUTIVE SESSION

The following were elected to membership Drs C J Lundy, of Detroit, W H Hotchkiss, of New Haven, H D Risley, of Philadelphia, David De Beck, of Cincinnati

OFFICERS FOR ENSUING YEAR

President—Dr J S Prout, of Brooklyn

Vice President—Dr George C Harlan, of Philadelphia

Secretary and Treasurer—Dr J J B Vermyne, of New Bedford, Mass

Representative to Executive Committee of Congress of American Physicians and Surgeons, Dr C R Agnew, of New York Alternate, Dr Wm H Carmalt, of New Haven

The Society then adjourned to meet at New London, Conn, July 19, 1888

AMERICAN OPHTHALMOLOGICAL SOCIETY

Twenty third Annual Meeting, held in New London, Conn, July 20 and 21, 1887

(*Continued from page 186*)

EVENING SESSION

DR W F NORRIS, of Philadelphia, reported some

CASES OF ACUTE PRIMARY GLAUCOMA, OF HÆMORRHAGIC GLAUCOMA, AND OF SECONDARY GLAUCOMA

Case 1—A married woman, aged 52 years, was admitted to the hospital with acute glaucoma of the left eye The attack was of twelve days' duration Vision was much impaired The right eye was entirely quiet and presented a narrow iridectomy upwards In August, 1875, a severe attack of glaucoma had suddenly occurred in the right eye, and on the fifth day iridectomy had been performed Since then the eye had given no trouble When admitted to the hospital, the patient was in a feeble condition She was put to bed, a leech applied and eserine instilled The eye improved and became quieter The cloudiness of the cornea and the other symptoms remaining, iridectomy was performed twenty-eight days from the commencement of the attack A year later, she had a severe attack of pain not relieved by eserine, and sclerotomy was performed The eye continued to give trouble from time to time, and it finally became necessary to enucleate it

Case 2—Miss B, aged 70 years, was seen in February, 1867, with marked hæmorrhagic retinitis and incipient cortical cataract She stated that she had a sudden loss of vision two years previously The present attack of loss of vision came on suddenly ten days before, when the patient was stooping Examination showed numerous hæmorrhages into the

retina. One month later, the right eye was more cloudy, the tension increased, and there was some hemorrhage into the anterior chamber Iridectomy was then performed The wound did well until the fourth day, when there was a sudden attack of pain On the ninth day, apparently without exciting cause, this symptom recurred After this there would be an exacerbation every few days The eyeball was subsequently enucleated, the patient dying a year or two later with apoplexy

Case 3—A man aged 66 had been operated on for cataract in both eyes some time before coming under observation This had been done in England, both operations having been successful Some eighteen months later, the right eye had been operated on by a needle operation, and since then it had not been free from irritation When seen, the right had lost the perception of light, and the left eye presented signs of sympathetic irritation The right eye was enucleated, and this relieved the irritation in the left eye The patient now sees fairly well

Dr H D Noyes said that in a case reported last year, dying on the fifth day, perfect approximation was prevented at one end of the incision by swelling of the scleral lip of the wound, which was double the thickness of the corneal lip Into the space so left the iris had been forced, thus illustrating the beginning of a cystoid cicatrix

Dr H Knapp asked whether the swelling of the scleral lip might not be due to the previous incarceration of the iris in the wound?

Dr Noyes believed that the use of the spatula in dressing the wound had left it free from iris

Dr B A Randall said that in Dr Noyes's case the anterior chamber must have been obliterated and the posterior capsule pushed forward, for the sections showed pigment attached to the posterior capsule

Dr B Alexander Randall, of Philadelphia, presented the notes of a case of

SARCOMA OF THE EYELID, SIMULATING MEIBOMIAN CYST,

occurring in a man about 41 years of age, who came under observation in 1885, with the history of two operations in the previous three years for the removal of a cyst The tumor had the position, size, color and apparent *fluctuation* of a chalazion, but a vague grayness suggested pigmentation, and led to its total removal by a V shaped incision through all the tissues of the lid Section proved the tumor to be a solid encapsuled sarcoma of large spindle cells The patient passed out of sight for two years, and then returned with recurrence very like the origin, which had been treated in the interim as chalazion The outer half of the lid had now to be removed, and the tumor was found to be of the same nature as before and again encapsuled The meibomian glands at both operations seemed to be entirely normal, and the tarsus was entirely uninvolved

Dr Randall also presented some cases of

CILIO RETINAL VESSELS,

with the remark that they were far from rare, and that the occurrence of such an origin of even a principal artery or vein, supplying different quadrants of the retina, had come to notice

Dr Randall called attention to the

HORI SCHNITT OF V JAEGER IN CATARACT EXTRACTION

as differing in no essential from the modified linear extraction, except in the knife with which it is made He asked attention to the knife, with the claim that with it almost all the usual modifications of the linear extraction could be made, but that no aqueous need be lost until the completion of the incision, and consequently that the cut could be made more safely and smoothly than was possible with the Graefe knife

Dr Knapp had used Jaeger's knife, but thought it harder to manage because of its greater size With the Graefe knife one can withdraw slightly and rectify any mistake in the position of the counter puncture

Dr H D Noyes agreed with the last speaker as to the superiority of the Graefe knife He had long practised a manœuvre which he found Panas also employed after making the counter-puncture, the handle is rather depressed, so as first to make the portion of the section adjacent to the counter puncture This quickly carries the cutting edge of the knife to the border of the anterior chamber, where the iris can no longer fall before it Then the handle of the knife is raised as the section is completed

Dr S Theobald, of Baltimore, thought the greater convenience of the narrow knife due to the fact that with it we can first make the counter puncture, and afterward complete the section, with the broad knife both must be done at once

Dr Randall said that if the puncture is made right, with the knife in the proper position, the counter-puncture must of necessity be right also, and the incision made is perfectly smooth

Dr Knapp thought that a broad knife acts more as a chisel, tending to push the cornea before it

Dr E Gruening was of the opinion that the difficulty about making a counter puncture is that its location is not seen, and when an attempt is made to correct its position, aqueous escapes and the iris is apt to fall before the knife

---

Thursday, July 21—Second Day

Dr H D Noyes, of New York, reported a

CASE OF GLIOMA OF THE RETINA

The patient, a child, was first seen when 15 months old The eye was enucleated and microscopical examination confirmed the diagnosis of glioma which was made prior to operation The patient was again seen fourteen and one half years later, when 16 years of age An artificial eye had been worn There was not the slightest evidence of a return of the disease

PSEUDO GLIOMA

This case was reported on account of the interest connected with the diagnosis It was difficult to say positively whether or not there was an intra ocular tumor The case was examined by Dr H Knight and the author, and a diagnosis of inflammatory trouble was made Enucleation was advised on account

of the doubt as to the correctness of the diagnosis, and even if the affection was purely inflammatory, enucleation was the wisest plan in view of future possibilities The patient was a boy aged 5 years, who in November, 1886, had fallen from his velocipede, the handle of the machine causing a wound of the left cheek under the orbit There was no apparent injury to the eye, and during the following winter there was no trouble On May 4, 1887, he was first seen by the author There was at this time a cicatrix one inch below the border of the left orbit No irregularity of the orbital edge could be detected, and pressure on the globe caused no pain The movements of the eye were normal and the pupil active, the iris had a slightly greenish hue An extremely vascular growth was seen with ease This seemed to fill the fundus After consultation it was deemed advisable to enucleate the eye This was done, the wound healing promptly Examination showed that there had been cyclitis with inflammation of the vitreous, with the production of inflammatory tissue extending across the eye behind the lens, forming a perfect septum The retina was totally detached and the choroid was partially detached There was also marked hypertrophy of the tissues at the base of the orbit It was thought that the original process had been an injury to the floor of the orbit

DR NOYES also reported a case of

PROLAPSE OF THE LACHRYMAL GLAND

C S, aged 20 years, consulted him on account of a swelling in the upper lid of the right eye This had been growing for nine years It could be freely moved over the globe an moved with movements of the eyeball There was no history of injury or of inflammation of the eye The mass was removed and found to be a displaced lachrymal gland The removal has been followed by no unpleasant effects Four cases of displacement of the lachrymal gland are on record

OPERATION FOR THE RELIEF OF ENTROPION OF THE LOWER LYLID

While in theory the operations for the relief of this condition are very simple, yet in practice they often fail to accomplish the desired end The author then described an expedient which he had employed four years ago He excised a piece of skin below the border of the lid and then dissected up a flap, leaving an open wound He next freshened a spot on the outer border of the lower lid, taking out a piece of conjunctiva He then turned the flap upward and attached it to the freshened surface This little flap served to hold the lid in a position of eversion In one week the stitches were removed The patient then disappeared and was not seen for four years It was then found that the lid remained in a natural position The little bridge of skin was still present, and under it there was a sinus through which a probe could be passed The piece of skin was divided and the result was perfect

DR SAMUEL THEOBALD In connection with the case of glioma, I would mention one that has gone nine and one half years without a return The only weak point in the case is that no microscopical examination was made The macroscopical appearances were, however, characteristic The operation was done when the boy was 6 years of age The boy is still perfectly well and there is no suggestion of the return of the disease

DR H KNAPP Until lately I have held the view that there was such a thing as the permanent cure of glioma, but now I am very doubtful if this is ever accomplished There are exceptional cases which do not terminate fatally until ten or fourteen years after operation They then die from a return of the local disease or else from a generalization of the condition Graefe said that all of these cases died

DR EMIL GRUENING I have seen two cases in which there has been an apparent immunity from the return of glioma The first case was operated on in 1875, the patient was a girl 5 years of age The optic nerve was not involved The girl is still under observation and in perfect health The second case, a child 1 year old, was operated on in May, 1880 It was a case of true glioma, with no involvement of the optic nerve The child is still perfectly healthy Both of these patients have been wearing artificial eyes since the operation

DR JOHN GREEN, of St Louis I have found most of the operations for entropion of the lower lid unsatisfactory I have in a general way followed Panas' recommendation of making an incision below and bringing the lid down by the use of sutures I have extended this operation by the following procedure After inserting the sutures, I make a cut a little inside of the border of the lid, carrying it through the whole thickness of the tarsal fibrous tissue When this is done the sutures are much more effective, and I find that there is no tendency for cicatricial contraction to occur in the process of healing The results obtained by this method have been eminently more satisfactory than those obtained by any other procedure

DR W F MITTENDORF, of New York, reported a

PHENOMENAL PULSATION OF THE INTERIOR OF THE EYE

The patient, 15 years of age came under observation for asthenopic trouble He showed no signs of disease The tension of the eye was normal and the fundus was normal There was no pulsation of the arteries or veins, but pulsation could be induced by pressure A short distance above the disc there was a grayish-white band stretching from one vein to another, and looking like a little sac filled with fluid It presented distinct pulsations, which corresponded with the cardiac pulsations The patient was seen a number of times, and the appearance was always the same A little higher up and more to the nasal side there was a similar band connected with an artery This did not pulsate except when pressure was made It was thought that the band was composed of connective tissue, which was thrown into vibration by the meeting of the vibration of the two veins with which it was connected

DR LUCIEN HOWE, of Buffalo, read a paper on

INCREASE OF BLINDNESS IN THE UNITED STATES

Attention was called to the fact that, while the population during the ten years from 1870 to 1880 increased at the rate of 30 per cent, blindness during the same time increased over 140 per cent By means of a diagram this percentage of increase in each State separately was shown The statistics also show that blindness increased in an almost constant ratio from north to south in the United States, and that it decreased in the same way from east to west This was also shown by colored maps As for the causes, contagion was found to exercise the most important influence Immigration was also considered as an important factor in view of the large number of contagious diseases of the eye introduced every year into the country, and the laxity or absence of quarantine regulations regarding them As for the prevention, suggestions were offered, *first*, as to the care of newborn children, *second*, the isolation of suspicious cases in residential schools and other institutions, even for adults also, *third*, the instruction of the public as to the advisability of guarding against contagious forms of disease

In connection with this matter, Dr Howe offered the following

WHEREAS, The census reports indicate that there has been an increase in the number of blind in the United States, more than four times as great as that of the total population, and

WHEREAS, An inquiry as to the causes of this shows that it is largely due to contagious diseases of the eye, therefore

Resolved, That a committee of three be appointed to examine further as to this apparent increase, and recommend means for its prevention

Resolved, That the President of the United States and the Secretary of State be respectfully requested to furnish this committee with whatever letters or other recommendations may be necessary to further their investigations in this country or elsewhere

Resolved, That the officials in charge of residential schools and similar institutions also be requested to assist the committee to any extent in their power

These resolutions were adopted, and the President appointed Dr Lucien Howe, of Buffalo, as chairman of the committee, the other members to be appointed subsequently

(*To be concluded*)

CHICAGO MEDICAL SOCIETY

Stated Meeting, May 2, 1887

DR F C HOTZ read a paper on

THREE CASES OF SYMPATHETIC OPHTHALMIA ARRESTED BY EARLY ENUCLEATION OF THE INJURED EYE

(See page 202)

DR FRANKLIN COLEMAN The point that Dr Hotz has taken up is one of the most interesting in regard to sympathetic ophtalmitis The necessity for enucleation is very definitely settled when the second eye is in an irritable condition One objection to enucleation is death I have lost one case from meningitis after enucleating an eye, with ophthalmitis I do not think deformity should be taken into consideration Out of seven cases of sympathetic ophthalmia five improved after enucleation of the exciting eye I have never seen an unfavorable result to vision follow I have not seen the second eye get any worse after operation on the first and I have not seen an eye with sympathetic ophthalmia get better without operation McKenzie fifty years ago, before enucleation was practiced, said he never saw an eye recover from sympathetic ophthalmia I wish to ask Dr Hotz whether he thinks that microorganisms generally produce sympathetic ophthalmia? If so, when the organisms have traveled from the first eye to the second, how would it benefit the *second* eye to remove the first?

DR W T MONTGOMERY There is one point that has not been referred to, that is, constitutional treatment I think it is the rule to give mercury in sympathetic trouble I am in the havit of enucleating the injured eye if it is blind, no matter what form the sympathetic inflammation has assumed I think that constitutional treatment is very important, and it is my practice to bring the patient under the influence of mercury as soon as possible in all cases of sympathetic ophthalmia, whether the injured eye has been enucleated or not

DR R TILLEY In 1883 the Ophthalmological Society of Great Britain referred to a committee the question of the general history of sympathetic ophthalmitis The committee appointed proposed a series of questions to the members of the Society The first of these questions was Given a case of sympathetic ophthalmitis, does the enucleation of the exciting eye modify the course? The committee took three years to consider the question, and after accumulating 200 cases among the published and unpublished cases that could be obtained among their fellow members and throughout literature, they decided that they were unable to formulate an answer to the question One conclusion that they came to was that the enucleation of the eye in the given condition did not seem to be detrimental to the general course of the sympathetic ophthalmitis It is true that Mauthner claims when sympathetic ophthalmitis is fully developed, at any rate certain forms of it, the eye should not be enucleated But I think the first case referred to, and the second case, which was similar, would really come under the class that Maunther would call irritation, and that, he would claim, should be unquestionably enucleated, because he distinctly says that in sympathetic irritation, especially where the sight of the exciting eye is gone, enucleation is absolutely demanded To determine just where sympathetic irritation leaves off and sympathetic inflammation begins is a difficult point The definition of sympathetic ophthalmitis given by the committee appointed by the Society of Great Britain was, turbidity of the vitreous or irido choroiditis plastica, keratitis punctata, iritis with adhesions, etc They distinctly say that they exclude simple sympathetic irritation, the reason being, as I understand it, because the opinion is fully established that with a condition of sympathetic irritation, especially where the sight is absent in the exciting eye, enucleation is the rule without any exception whatever I infer that Dr Hotz thinks that microorganisms are always present where sympathetic ophthalmia exists That

question seems still as unsettled as the question of enucleation in a case of sympathetic ophthalmia I think Alt recently reported a case where he searched most assiduously for the presence of microorganisms in the enucleated eye, but was unable to find any I think it very unlikely that sympathetic ophthalmia should always travel through the optic nerve

DR FRANK BILLINGS It is true, as Dr Hotz has stated, that the staphylococcus pyogenes aureus has been found in sympathetic inflammation of the eye, it is the organism that is almost always found wherever there is pus present So often is it found that, wherever we have an abscess, we can expect to get a culture of this organism The experiments of Deutchmann, as given by Dr Hotz, are on record in the reports of the Kaiserlichen Gesundheits Amt Other experiments were carried out after he made his statements, that is injections were made of the staphylococcus pyogenes aureus with the object in view of seeing if it would excite a sympathetic ophthalmia These experiments were made on rabbits, but not always with success, wherever suppurative inflammation resulted in the eye, then sometimes the sympathetic ophthalmia arose on the other, but not always, the subject is unsettled, and must remain so Mistakes have been ascribed to the experiments already made, that they were careless in making their cultures, that perhaps they did not get that particular culture from the inflamed eye The true culture of the staphylococcus pyogenes aureus would be of an orange color, and further, if the culture did grow within the eyeball, it would cause suppuration

DR HOTZ I did not say in my paper that I accepted Deutchmann's view that sympathetic ophthalmia is an infectious disease I have not made any experiments myself, and this question is so new and so difficult to settle that it would be premature to decide on the experiments so far made and to assert that sympathetic inflammation is always the result of the immigration of microorganisms I referred to these experiments of Deutchmann simply as an interesting illustration showing that in one way, at least, sympathetic inflammation can be produced, and that it always shows itself in the second eye in the optic nerve first These are questions which I did not propose to discuss in this paper

In reference to the statement made by one of the speakers that I did not give a clear definition of what I meant by sympathetic inflammation From his remarks I should infer that he would not consider as the beginning of sympathetic inflammation such a condition as I described in the first and second cases But I thought it was clear that if the optic nerve is not only hyperæmic, but its outlines indistinct and the papilla swollen, showing that there is more than an engorgement of the blood vessels, this condition of the nerve has passed the stage of irritation, that there is actually an active inflammation going on, we have an active neuritis and not simply an irritation I consider this is the first stage of sympathetic inflammation What I would call sympathetic irritation would refer to such disturbances in the second eye as sensitiveness to bright light or disability to use the eye on account of pain, in reading, a painful accommodation as I may call it, an impossibility of accommodating the eye in reading for any length of time, while the eye appears absolutely normal shows no evidence of inflammation, externally or internally Such a condition is sympathetic *irritation*, and as far as I know it never passes over into sympathetic *inflammation* It can go on for months and never disturb the eye in any other way, and you will see at once this is a very different condition from anything I referred to Sympathetic irritation can always be relieved by the removal of the exciting eye, no matter how long it has been going on But in sympathetic inflammation there is great danger in delay, it cannot be arrested when advanced very far, but it can be in the incipient stage That is what I tried to prove by my paper to night.

LEIPZIG AND DRESDEN[1]

Thiersch—Spondylitis—Tubercle Bacilli and Suppuration—Osteo Myelitis—Ion Lesser—Stelzer—Fragments of Wood in the Bowels—Foreign Body in the Heart—Tubercular Osteo Myelitis—Vaginal Hysterectomy for Carcinoma—Leopold

Dear Dr Fenger —From Halle I went to Leipsig for the purpose of spending a few days in the surgical wards of Professor Thiersch I came in time to attend the opening lecture of the Spring term and soon became convinced that this famous surgeon had passed the zenith of fame and usefulness, and is rapidly approaching senile marasmus physically and mentally Thiersch has immortalized himself by his many ingenious plastic operations and his classical work on Epithelial Carcinoma, as well as by many other valuable contributions to surgical literature It is a great pity that such men, for the sake of science, grow old too soon, but such is life, short in its duration, and the greatest genius must submit to the inevitable consequences incident to old age During my former, as well as on this, visit to Europe I have been repeatedly reminded of the fact that when a man arrives at a certain age it would be better for himself, for his reputation, and more especially for the school he represents, to retire Langenbeck appreciated this fact and retired at the time when he was still in the possession of all of his faculties to make room for a man younger in years The sooner Theirsch follows his example the better for himself and the students There are many younger men in Germany who would bring more enthusiasm into the lecture room, and who are well prepared to become the successor of this eminent surgeon

In his introductory lecture he advised his students to take full notes on the cases presented in the clinic so as to preserve the material thus gained for future use and reference The subject of his clinic was spondylitis, and he presented a number of cases to illustrate the different stages of the disease He called attention to the fact that tubercular inflamma

INTERNATIONAL CONGRESS

XV SECTION, ON PUBLIC AND INTERNATIONAL HYGIENE

Provisional Organization

Provisional Programme of Proceedings, Papers, and Discussions, prepared by Joseph Jones, M D, of New Orleans, Provisional President of Section, Public and International Hygiene

FIRST DAY, SEPTEMBER 5, 1887

1 Call to order by the President

2 Registration of the officers and members

3 Registration of the members of the Congress who may desire to read papers before the Section on Public and International Hygiene, and take part in its deliberations

4 Formal presentation by the President of the names of the officers and members of the Council of this Section, with the titles of the essays and papers to be read and discussed

5 Announcement of the titles of voluntary papers and essays to be presented to this Section for discussion

6 Reports of Vice Presidents Reports of Secretaries

7 Address by the President on "Public and International Hygiene"

SECOND DAY, SEPTEMBER 6

1 Reading of Minutes

2 Registration of officers and members

3 Announcement of order of business and reading of titles and papers

PAPERS AND DISCUSSIONS

1 Reading of paper by Richard H Day, of Baton Rouge, La, entitled "Report of an Inquiry into the Facts Relating to the Effects of Overflows of the Mississippi River and its Tributaries, and Rice Culture, upon the Public Health, and the Best Means of Controlling these Baleful Influences"

2 Discussion of the paper of Dr R H Day

3 Discussion of the Various Systems of Drainage and Sewage now employed in Europe and America

4 Reading of paper by Dr Leighton, entitled "The Place of Sanitary Science in Education, in which will be Briefly Sketched—

(*a*) The History of a Human Life, and note its Bearing on our Educational Deeds

(*b*) Recall the Character Impressed upon Education by the Various Civilizations of the Past, and in the Light of such Past Experience Discuss some of the Elements of Strength and Weakness in our American Civilization, and consequently in the Controlling Ideas which Dominate our Civilization

(*c*) Adhering as closely as possible to Ways and Means already Established, show how these various Educational Measures may be Utilized and Gradually Modified, so as Practically to Popularize Sanitary Notions, within their Personal and Public Aspects, with the least Radical Changes, and with due Recognition also of the Claims of other more and even less Important Training and Interests"

5 Discussion of the paper of Dr A W Leighton, embracing the subject of *Sanitary Education*

6 Paper by Dr W K Fort, of New Orleans, entitled "The Necessity of Public Hygiene to institute Efforts to suppress Syphilis, one of the Most Potent Agents of Destruction to Mankind"

7 Discussion of Dr Fort's paper

8 Discussion as to the Existence and Micro organism of Syphilis

9 Discussion of the measures best adapted to the Prevention and Modification and Arrest of Syphilis

10 Discussion of the Relation of Syphilis to Vaccination

11 Reading of volunteer papers and essays

12 Discussion of volunteer papers and essays

13 "The Application of Chemical Methods and Science to the Solution of Various Problems Relating to Public and International Hygiene," by Prof J W Thudichum, of London

14 Discussion of the paper of Dr Thudichum

15 Discussion of the Relations of Chemical Science to Public and International Hygiene

THIRD DAY, SEPTEMBER 7

1 Reading of Minutes

2 Registration of officers and members

3 Announcement of order of business and reading of titles and papers

PAPERS AND DISCUSSIONS

4 "The Cause and Prevention of Typhoid Fever, with Delineation of the Micro organisms of Typhoid Fever," by Dr Antoine Magnin, of France

5 Discussion of Professor Magnin's paper

6 Discussion of the Origin, Natural History, Relations to the Public Health, and Prevention, of Typhoid Fever

7 "Sobra un Bacillo Malarie, Natura della Malaria, sulla Preservazione dell' Uomo per paresi di Malaria," by Prof Tommasi Crudeli, Professor of Hygiene in the University of Rome, Italy

8 Discussion of the paper of Dr Tommasi Crudeli, and of the Facts and Theories Relating to the Cause, Nature, and Prevention of Malarial Fever

9 "Le Vaccin de la Fièvre Jaune, Resultats Statistiques des Inoculations Practiqués avec la Culture Attenuée du Microbe de la Fièvre Jaune" par le Dr Domingos Friere, of Rio de Janeiro, Brazil

10 Discussion as to the Nature of the Microbe of Yellow Fever, and the Nature and Value of Vaccination with Attenuated Cultures of the Yellow Fever Virus, as practiced by Professor Domingos Friere, of Brazil, for the modification and prevention of the disease

11 "L'étiologie et la Prophylaxie de la Fièvre Jaune," par Dr Manuel Carmona y Valle, of the University of the City of Mexico, Republic of Mexico

12 Discussion of the Method of Professor Carmona, for the Modification, Prevention and Arrest of Yellow Fever

13 "Outline of Investigations relating to the Causation and Prevention of Endemic and Epidemic Diseases, and more especially Malarial Fever, during a Period of Thirty Years, with a Claim for the

of age, and a multipara The disease had existed for some time, but appeared to be limited to the cervix Thorough antiseptic precautions were observed before and during the operation The patient was placed in exaggerated lithotomy position and the uterus rendered accessible with retractors Instead of forceps sharp double hooks were used for bringing the uterus down The vaginal roof close to the insertion of the uterus was incised with the scapel and the organ detached with blunt instruments and scissors Where hemorrhage was expected the incision was made between two ligatures The peritoneal cavity was first opened in front of the uterus but as it was found impossible to antevert the fundus sufficiently to bring it out through the wound the cul de sac of Douglas was opened, and the fundus brought out through this opening The round and broad ligaments were tied separately before they were divided After the uterus was removed the omentum came down into the vagina and after thorough disinfection it was reduced and the vaginal canal plugged with iodoform gauze Duration of operation about an hour and a half

I visited the gynecological and obstetrical wards in charge of Professor Leopold, and was promised a laparotomy for next day I was asked to come perfectly aseptic, which request I carried out conscientiously, including bath, shampooning, etc , but was informed next morning that inasmuch as the city was celebrating the King's birthday, the operation would be postponed As Dr Stelzer performed his vaginal hysterectomy an hour later it could not have been considered a crime in Dresden to perform a surgical operation on such an eventful day, and I made up my mind that a surgeon who postpones on such flimsy grounds cannot be troubled with many operations during the year, consequently I did not wait to test the reliability of the second promise, but lost no time in transporting the aseptic *ego* to a more profitable place N SENN

DOMESTIC CORRESPONDENCE

UNPROFESSIONAL CONDUCT OF RAILWAY SURGEONS

Dear Sir —While the poet has said,

> *The rank is but the guinea stamp,*
> *The man's the gowd for a' that,*

the world concedes the importance of the stamp Germane to your editorial on, "Medical Rank in the Navy," we desire to remark, "We have heathen nearer home" For a quarter of a century, by resolution and memorial, the American Medical Association has been endeavoring to dignify the profession, and to protect American seamen by providing surgeons for ocean steamers and by giving to the medical officers of the Navy a rank and pay proportionate with the acquirements and services demanded, and yet the Surgeon General reports, "It is impossible with the present inducements offered to find young men, possessing the necessary qualifications, who are disposed to become medical officers in the Navy"

Meanwhile there has grown up a system of land transportation that carries more passengers in one day than our marine service transports in a month, and liable to accidents and injuries that can hardly occur on the water Some of our great railroads, recognizing the danger to which its employes and passengers are constantly exposed have appointed men of distinguished professional ability as "chief surgeons," and in every considerable town along the lines of their roads the best resident practitioners as "local surgeons," paying them an honorarium commensurate with the services rendered and tendering the compliment of an employee's pass, thus assuring to the traveling public and to their employes the best possible surgical skill in case of accident

Other great roads, with the greed too often common to monster corporations, or with a deplorable ignorance of the importance to themselves and the public, have appointed as chief surgeons men whose respect for their profession permits them to send to doctors along the line of their roads this contract

> For and in consideration of a pass over the —— division of the —— & —— road I agree to render all the professional services required by such road and by the Hosp department of the road in —— county, state of ——
> WITNESS

While on these roads every other employe, from the president to the section boss, in addition to his salary, can get a pass for the asking, the surgeon, who, if he has any practice, rarely has occasion to ride, except in the service of the road, and whose services require the highest skill and are fraught with the gravest results, is placed beneath the lowest employe of the road and tendered for his services a pass What a regard for his profession must such a chief surgeon have, and what a soul!

Unlike applications for appointments in the Navy such roads do not require precedent examinations and "necessary qualifications," and hence have no lack of applicants

While some good men accept their appointment to maintain their professional standing among a people who without knowledge of the emptiness of the honor look upon it as evidence of merit, an overcrowded profession gives and abundance of supplicants who need opportunity for surgical practice

The chief surgeon of a rich corporation who would ask skilled and valuable services from his professional brethren for nothing, while he receives a salary far above his professional worth, should receive the condemnation of every honorable member of the profession, and the chief surgeon of a great railroad who would appoint cheap doctors, because they are cheap, to a position that might place under their care any man in the nation from its chief Executive down merits the execration of the whole people

If the American Medical Association feels that the honor of the profession and the protection of the people is involved in appointing competent surgeons to our ocean steamesrs and in securing suitable rank and pay to the medical officers of the Navy, has it not a parallel interest in the qualification and position of the local surgeons of the great railroads of the country? W

INTERNATIONAL CONGRESS

XV SECTION, ON PUBLIC AND INTERNATIONAL HYGIENE

Provisional Organization

Provisional Programme of Proceedings, Papers, and Discussions, prepared by Joseph Jones, M D, of New Orleans, Provisional President of Section, Public and International Hygiene

FIRST DAY, SEPTEMBER 5, 1887

1 Call to order by the President

2 Registration of the officers and members

3 Registration of the members of the Congress who may desire to read papers before the Section on Public and International Hygiene, and take part in its deliberations

4 Formal presentation by the President of the names of the officers and members of the Council of this Section, with the titles of the essays and papers to be read and discussed

5 Announcement of the titles of voluntary papers and essays to be presented to this Section for discussion

6 Reports of Vice Presidents Reports of Secretaries

7 Address by the President on "Public and International Hygiene"

SECOND DAY, SEPTEMBER 6

1 Reading of Minutes

2 Registration of officers and members

3 Announcement of order of business and reading of titles and papers

PAPERS AND DISCUSSIONS

1 Reading of paper by Richard H Day, of Baton Rouge, La, entitled "Report of an Inquiry into the Facts Relating to the Effects of Overflows of the Mississippi River and its Tributaries, and Rice Culture, upon the Public Health, and the Best Means of Controlling these Baleful Influences"

2 Discussion of the paper of Dr R H Day

3 Discussion of the Various Systems of Drainage and Sewage now employed in Europe and America

4 Reading of paper by Dr Leighton, entitled "The Place of Sanitary Science in Education, in which will be Briefly Sketched—

(*a*) The History of a Human Life, and note its Bearing on our Educational Deeds

(*b*) Recall the Character Impressed upon Education by the Various Civilizations of the Past, and in the Light of such Past Experience Discuss some of the Elements of Strength and Weakness in our American Civilization, and consequently in the Controlling Ideas which Dominate our Civilization

(*c*) Adhering as closely as possible to Ways and Means already Established, show how these various Educational Measures may be Utilized and Gradually Modified, so as Practically to Popularize Sanitary Notions, within their Personal and Public Aspects, with the least Radical Changes, and with due Recognition also of the Claims of other more and even less Important Training and Interests"

5 Discussion of the paper of Dr A W Leighton, embracing the subject of *Sanitary Education*

6 Paper by Dr W K Fort, of New Orleans, entitled "The Necessity of Public Hygiene to institute Efforts to suppress Syphilis, one of the Most Potent Agents of Destruction to Mankind"

7 Discussion of Dr Fort's paper

8 Discussion as to the Existence and Micro organism of Syphilis

9 Discussion of the measures best adapted to the Prevention and Modification and Arrest of Syphilis

10 Discussion of the Relation of Syphilis to Vaccination

11 Reading of volunteer papers and essays

12 Discussion of volunteer papers and essays

13 "The Application of Chemical Methods and Science to the Solution of Various Problems Relating to Public and International Hygiene," by Prof J W Thudichum, of London

14 Discussion of the paper of Dr Thudichum

15 Discussion of the Relations of Chemical Science to Public and International Hygiene

THIRD DAY, SEPTEMBER 7

1 Reading of Minutes

2 Registration of officers and members

3 Announcement of order of business and reading of titles and papers

PAPERS AND DISCUSSIONS

4 "The Cause and Prevention of Typhoid Fever, with Delineation of the Micro organisms of Typhoid Fever," by Dr Antoine Magnin, of France

5 Discussion of Professor Magnin's paper

6 Discussion of the Origin, Natural History, Relations to the Public Health, and Prevention, of Typhoid Fever

7 "Sobra un Bacillo Malariæ, Natura della Malaria, sulla Preservazione dell' Uomo per paresi di Malaria," by Prof Tommasi Crudeli, Professor of Hygiene in the University of Rome, Italy

8 Discussion of the paper of Dr Tommasi Crudeli, and of the Facts and Theories Relating to the Cause, Nature, and Prevention of Malarial Fever

9 "Le Vaccin de la Fièvre Jaune, Resultats Statistiques des Inoculations Practiqués avec la Culture Attenuée du Microbe de la Fièvre Jaune" par le Dr Domingos Friere, of Rio de Janeiro, Brazil

10 Discussion as to the Nature of the Microbe of Yellow Fever, and the Nature and Value of Vaccination with Attenuated Cultures of the Yellow Fever Virus, as practiced by Professor Domingos Friere, of Brazil, for the modification and prevention of the disease

11 "L'étiologie et la Prophylaxie de la Fièvre Jaune," par Dr Manuel Carmona y Valle, of the University of the City of Mexico, Republic of Mexico

12 Discussion of the Method of Professor Carmona, for the Modification, Prevention and Arrest of Yellow Fever

13 "Outline of Investigations relating to the Causation and Prevention of Endemic and Epidemic Diseases, and more especially Malarial Fever, during a Period of Thirty Years, with a Claim for the

Comprehensive Demonstration of the Chemical, Microscopical, and Pathological Characters of the Blood and Organs in Malarial Fever, and the Application of the results of these Investigations to the Diagnosis of Diseases, and to Medico-legal Science," by Joseph Jones, M D, of New Orleans, La

14 "The Influence of Climate in the Production of Cholera Infantum," by George Troupe Maxwell, of Ocala, Florida

15 Discussion of paper by Dr Maxwell

16 Discussion of the causes of Diarrhœa and Dysentery, of the measures of Public Hygiene, best adapted to their prevension

17 Discussion as to the present state of our knowledge with reference to the mode of origin and spread of Asiatic Cholera

18 Discussion of the nature and value of the Methods of Disinfection and of Sanitation employed for the arrest of Asiatic Cholera

19 Discussion of the mode of performance, and the value of vaccination with the attenuated virus of Asiatic Cholera, for the Modification and Arrest of Asiatic Cholera

20 Relations of Asiatic Cholera in its Origin and Propagation to climate, soil and sanitary conditions

21 "Public Hygiene," by Dr Benjamin Ward Richardson, of London

22 Discussion of paper by Dr Richardson

23 Discussion of the hygiene of Public Institutions, buildings, hospitals, barracks, prisons, penitentiaries and jails

24 Discussion of the question of the establishment of uniform hygienic rules for the conduct of civil and military prisons, and for the humane treatment of military prisoners, in accordance with hygenic laws, and for the prompt and uniform exchange of prisoners of war

FOURTH DAY, SEPTEMBER 8

1 Reading of minutes

2 Registration of officers and members

3 Announcement of order of business and reading of titles and papers

PAPERS AND DISCUSSIONS

4 "Discussion of the Causes of Typhus Fever in the Prisons and Hospitals during the American Civil War, 1861–1865," by D W Hand, of St Paul, Minnesota

5 Discussion of the facts illustrating the origin and mode of propagation of Hospital Gangrene, Erysipelas and Pyæmia in military hospitals and prisons

6 "Military Hygiene," by M K Taylor, M D, Major and Surgeon, U S A, San Antonio, Texas

7 Discussion of paper by Dr Taylor

8 Discussion of subjects relationg to Military and Naval Hygiene

9 Demonstrations of portable apparatus for water analysis

10 Reports of Committees

11 Reading of Volunteer papers

12 "Relations of Race to the Origin and Propagation of various Diseases," by Professor E D Mapother, M D, of Dublin, Ireland

13 Discussion of the paper of Professor Mapother and of the following subjects

(*a*) The relative Mortality of the different Races of Mankind as influenced by Physical Constitution, Germinal Forces, Climate, Soil, Food, Occupation, Domestic Habits and Sanitary Conditions

(*b*) Relative rates of Increase and of Mortality amongst the white and colored Races in Africa, in the West Indies, in Brazil, in Mexico, and in the United States of America

14 "The History and Practical Application of Steam as a Disinfectant—

(*a*) The degree of Temperature and Time required

(*b*) Mode of Application

(*c*) Practical Results" By Vice-President A N Bell, of New York City, N Y

15 Discussion of the paper of Dr Bell

16 Discussion of the relative value of Dry Heat, Dry Air, Moist Air, Steam, and superheated Steam, in the disinfection of infected Ships, Houses, and articles of Furniture and Clothing

17 Description and demonstration of the various forms of Apparatus adapted to the application of Heat to the disinfection of infected Ships, Houses, and articles of Furniture, Beds, Bedding, Clothing, etc

18 Discussion of the relative value of the more important Disinfectants and Germicides, as Bichloride of Mercury, Carbolic Acid, Sulphate of Iron, Sulphate of Copper, Red Oxide (binoxide) of Mercury, Sulphurous Anhydride (sulphurous acid), and Chlorine, Iodine and Bromine

19 Discussion of the relative value of the various methods of Disinfection, Detention, and Isolation, employed at the National and State Quarantine Stations of Portugal, Spain, Italy, France, Austria, Germany, Turkey, Russia, England, United States of America, Republic of Mexico, Central, South, and Insular America

20 Discussion of the facts showing the necessity on the part of all civilized Nations of formulating and adopting uniform Rules and Regulations governing Quarantine, modified and adapted to the Climate, and to the Endemic and Epidemic Diseases of different Countries

FIFTH DAY, SEPTEMBER 9

1 Reading of minutes

2 Registration of members

3 Reports of Secretaries

4 Reports of committees

5 Announcement of titles of papers and order of business

PAPERS AND DISCUSSIONS

6 "A new method of testing the Germicidal and Antiseptic Powers of certain Mineral and Vegetable Substances, employed externally and internally, in the treatment of Wounds, Tumors, Enlarged Glands, Ulcers, and Syphilis, and in certain Sanitary Operations of Domestic and Public Hygiene," by Joseph Jones, M D, of New Orleans, La

17 Discussion of the paper of Dr Joseph Jones

18 Discussion of previous question relating to the

methods employed by Chemists, Physiologists, and Microscopists, to determine the nature and mode of propagation of the Causes of Infectious and Contagious Diseases

9 "Subjects relating to Public Hygiene," by W C Cook, M D, of Nashville, Tenn

10 Discussion of the paper of Dr Cook

11 "On the Relations of State Medicine to Medical Jurisprudence," by W L Schenck, M D, of Osage City, Kansas

12 Discussion of the paper of Dr Schenck

13 "Sanitary Inspection of Railroads, and the Sanitation of Railroads, Cars and Stations," by R Harvey Reed, M D, of Mansfield, Ohio

The report of Dr R Harvey Reed "On the Sanitary Inspection of Passenger Coaches," will embrace the results of careful experimental investigation In the language of its author This report will be based upon the results of repeated personal examinations of the passenger coaches of a number of the leading American railroads, while in actual service, and will embrace the following

1 The Temperature
of the atmosphere outside of the coaches,
of the air inside the coaches while running,
of the air inside the coaches while standing
2 The Heating of the Coaches
(*a*) by stoves
(*b*) by hot air
(*c*) by hot water
3 The Ventilation of Coaches
(*a*) direction of wind outside of coaches
(*b*) currents of air through the coaches
(*c*) supply of fresh air
(*d*) exit of foul air
4 Lighting of Coaches
(*a*) by candles,
(*b*) by lamps,
(*c*) by gas
5 The chemical analysis of the Air in the Coaches
6 The chemical analysis of the Drinking water used in the Coaches
7 The use of Disinfectants
8 The supply of Tools, Water buckets, etc,
9 General Sanitary Condition
of the toilets,
of the hoppers,
of the urinals,
of the water closets
10 Conclusions and Suggestions

14 Discussion of the paper of Dr R Harvey Reed, Vice President

15 Discussion of the Sanitary Cordons of Railroads, and of International and Inter State Communication and Commerce, during the prevalence of Contagious and Infectious Diseases, such as Yellow Fever, Small Pox, Asiatic Cholera, and Oriental Plague

16 "Cremation," by Dr Felix Formento, of New Orleans La

17 Discussion of Dr Formento's paper

18 Discussion of the relative value, in a hygienic point of view, of the various modes of the Disposal of the Dead now prevalent in Civilized Nations

19 Discussion of the modes, and various Structures employed in the Cremation of the Dead

20 "A Practical and Common sense View of Public and International Hygiene, the Importance of the Work, What is Practicable? The Necessity of Harmony and Uniformity of Action among the States of this Republic in order to make effective the Work of the International Medical Congress to prevent Disease and contagious Epidemics," by Urial R Milner, M D, of New Orleans, La

21 Discussion of paper of Dr Milner

22 Reading of volunteer papers

23 Reports of committees

[NOTES—1 The preceding "Provisional Programme" of the papers and subjects for discussion during the sessions of the Section on Public and International Hygiene, is evidently subject to indefinite expansion It will be observed that under the head of Volunteer Papers and Essays, any registered member of the Ninth International Medical Congress will have an opportunity of being heard on any subject relating to Public or International Hygiene

2 The subjects proposed for discussion embrace a large amount of practical knowledge of vast importance to this Republic and to all civilized nations

3 The meetings of the Section on Public and International Hygiene of the Ninth International Medical Congress, to be held in Washington, D C, September 5, 1887, as indicated by the preceding "Provisional Programme," should be devoted exclusively to the reading and discussion of scientific papers and essays relating to the science and art of Public and International Hygiene

4 All officers and members of the Council, and all individuals not included in these classes, who may desire to take part in the proceedings, *must first register as members* of the Ninth International Medical Congress

5 The daily registration of officers and members relates to those sitting for the first time in this Section, and is designed to prevent unnecessary confusion in the proceedings

6 This "*Provisional Programme of Proceedings of the Section on Public and International Hygiene*, is submitted as a contribution (the result of much labor and extensive correspondence), to aid those members of the medical profession who may desire to present papers or to engage in the discussions, with a full and respectful recognition of the powers of the Ninth International Medical Congress, which can and will, upon its formal assemblage in Washington, D C, *confirm or reject* all (or each and every) "Provisional Officers," "Sections," and "*Provisional Programmes*" of scientific work

JOSEPH JONES, M D,

156 Washington Avenue, Fourth District, New Orleans, La, July 21, 1887]

REDUCED RAILWAY RATES

The roads included in the "Western States Passenger Association" have offered the same reduction as already announced for other associations, that is one full fare going and one third fare returning on the certificate plan The following roads and associations require that their certificates shall be distributed by the undersigned to whom application should be made for them

Southern Passenger Association

Chicago & Alton Railroad Company
Illinois Central Railroad Company
Trunk Line Association, (the last named after Aug 20th)

As far as heard from the certificates are distributed, on all other roads, only by the agents of the roads and can be had on purchasing the tickets at the stations

It is important for members to bear in mind the following rules

1 Some of the roads will not sell return tickets earlier than three days prior to the meeting of the Congress

2 Members must secure receipts from the ticket agents at starting points for full fare to Washington or, as far as the company has jurisdiction, upon the certificate of the company

3 The going and return must be over the same route

Extract from rules of some of the "Western States Association," "Members passing over *two* or more railways en route to your meeting or who pay two or more short fares locally, on account of local tickets not being sold through, should procure receipts for the fare paid going over each line, or for each ticket purchased, as return tickets at the reduced rate will only be issued locally by each company and for same trips Blank forms for this purpose are in the hands of all station agents and will be issued as receipts for full fare paid on application

J W H LOVEJOY, M D,
Ch Com on Transportation
No 900 12th St, Washington, D C
Attest —C H A KLEINSCHMIDT, M D,
Secretary Com of Arrangements

The Northern Pacific R R Co and the St Paul, M & M R R will return members to any points on their lines for *one fifth* fare, full fare being paid on coming East to St Paul The certificates of these Roads are distributed by the Railroad Agents

The Union Pacific declines to make special rates The New England General Ticket and Passenger Association also declines

J W H LOVEJOY, M D,
Chairman Trans Com

EXCURSION RATES TO CALIFORNIA,—CORRECTION —Concerning the excursion rate for members of the Medical Congress and families from Niagara Falls to California, a mistake was made in announcement last week It will be about $95, and the sleeping car fare will be about $17 From Washington, via New Orleans, it will be about $100 This is round trip, and permits the excursionists to stop over a day at Salt Lake going and returning, via New Orleans and through Kentucky, visiting Mammoth Cave, etc Tickets good for six months

H M VANARMAN, T P A S P Co

EXHIBITS AT THE CONGRESS —All applications for space for Exhibits before the International Medical Congress should be addressed to Dr D C Patterson, Treasurer of the Committee of Arrangements and Chairman of Sub committee on Hall and place of meeting of Congress

---

MISCELLANEOUS

DR JOSEPH C HUTCHINSON, long known as the most eminent surgeon of Brooklyn, died in that city on July 17, aged 60 years

FOUL DRINKING WATER ON BOARD SHIP —Dr Harold C Ernst, the bacteriologist of Harvard University, to whom was submitted for analysis a vial of the water drunk by the passengers of the Allan Line steamship Prussian, which arrived at Boston from Glasgow a few weeks ago, made his report to the Board of Health He found evidences of dangerous impurities in the water, and that it was totally unfit to be drunk Sixty five of the Prussian's passengers were ill with typhoid fever when the vessel reached port

THE HEATING OF CARS—RAILWAY BRIDGES —Last month Gov Hill, of New York, signed a bill regulating the heating of steam cars The statute makes it unlawful for any steam railroad after May 1, 1888, to heat its passenger cars on any other than mixed trains by any stove or furnace kept inside the car or suspended therefrom, except it may be lawful in case of accident or other emergency to temporarily to use any such stove or furnace with necessary fuel Provided that in cars which have been equipped with apparatus to heat by steam, hot water, or hot air from the locomotive or from a special car the present stove may be retained to be used only when the car is standing still, and provided also that this act shall not apply to railroads less than fifty miles in length, nor to the use of stoves, of a pattern and kind to be approved by the Railroad Commissioners, for cooking purposes in dining room cars The law also provides that from Nov 1, 1887, floor systems shall be maintained on all bridges so constructed as to support a derailed locomotive or cars, with guard rails or timbers so constructed as to guide the wheels in case of derailment Guard rails shall be maintained upon the approaches to all bridges

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JULY 30 1887, TO AUGUST 5 1887

Col Chas Sutherland, Surgeon, leave of absence extended one month S O 174, A G O, July 29, 1887

Major B Fryer, Surgeon, relieved from further duty at Ft Lowell, Ariz S O 176, A G O, August 1, 1887

Major Lly McClellan, Surgeon, detailed as member of a board of survey, to meet at the Medical Purveying Depot, St Louis, Mo on August 1, 1887 S O 173, A G O, July 28, 1887

Major Harvey E Brown, Surgeon, relieved from duty in Dept Mo, and ordered to Jackson Bks, La, for duty at that post S O 174, A G O, July 29, 1887

Capt Jno de B W Gardiner, Asst Surgeon, granted leave of absence for one year, on surgeon's certificate of disability S O 177, A G O, August 2, 1887

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING AUGUST 6 1887

P A Surgeon Fairfax Irwin, to inspect unserviceable property at New York Marine Hospital, August 5, 1887

P A Surgeon H R Carter, granted leave of absence for six days August 1 1887

P A Surgeon A D Bevan, granted leave of absence for ten days August 6, 1887

Asst Surgeon Seaton Norman, granted leave of absence for four days on account of sickness August 5, 1887

CORRIGENDA

In THE JOURNAL of August 6, Dr Senn's letter, read *Geu mer* for Geugmer On page 188, 16th line from bottom, read *mer* for mt, and 15th line from bottom read *richtige* for rechtige

In THE JOURNAL of August 6, p 177, table of cases of abdominal section, case 22, column 5, for "fibroid tumor of uterus, 26 *lbs*", read 6 *lbs*

ORIGINAL ARTICLES

REPORT OF TWELVE CASES OF ALEXANDER'S OPERATION

Read in the Section on Surgery and Anatomy, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY J H KELLOGG, M D,

OF BATTLE CREEK MICH

Since October, 1886, I have performed the operation of shortening the round ligaments, known as Alexander's operation, twelve times My object in presenting a report of the cases operated upon is three fold 1 To elicit a discussion of the subject, 2 To record, as a part of the history of the operation, a number of successful cases, and, 3 To add a few original observations, and to call attention to what has in my experience seemed to be an improvement in the mode of operating

This operation has been brought forward as a desirable substitute for many of the operations and appliances which have so long been used in the treatment of procidentia and retro displacements Uterine prolapse in its various degrees, and backward displacement of the uterus are among the most common, and certainly not the most curable, of the ailments with which the gynecologist is called upon to deal It is true that relief may be afforded in most cases by means of a properly adjusted pessary, but it is also true that in all but a small proportion of cases in which relief is secured in this manner the pessary becomes a life long necessity, which is often attended by very great inconvenience, and is not infrequently productive of serious injury In many cases, a woman who is dependent upon a pessary to retain the uterus in proper position, is almost equally dependent upon a physician to inspect the appliance at stated intervals, or whenever discomfort is experienced In by far the great majority of cases also, it is found necessary to substitute for the old appliance one of larger size or different form, as each successive ring or lever or other device loses its efficiency by the stretching of the vaginal walls The statistics of the results of the mechanical treatment of these affections are such as to justify the statement that by this method there is little or no hope of radical cure, even after years of treatment In two series of cases of retroversion treated by eminent gynecologists, numbering 643 persons in all, only eight were reported cured by means of vaginal pessaries, and of prolapsus uteri, Thomas says frankly "The prognosis as to cure is very bad, and even as to complete relief is not good"

The unsatisfactory character of the results which have been attained in the treatment of this class of uterine affections by pessaries, is well attested by the many surgical procedures which have been suggested for their relief The numerous forms of elytrorrhaphy and colporrhaphy, to the list of which almost every leading gynecologist has contributed some modification, have successively promised wonderful results, but with the exception of the median colporrhaphy of LeFort, have all proven ineffective except in the most favorable cases As regards the results of the surgical methods which have been in vogue before the introduction of the method of Alexander, Dr T Gaillard Thomas says, "It is never safe to promise a good and permanent result from any of the operations of elytrorrhaphy"

When the claims of Dr Alexander for his operation of shortening the round ligaments were first brought forward, I felt exceedingly skeptical regarding the value of the procedure, but after making some careful dissections of the parts involved in the operation, I became convinced that my skepticism was largely the result of ignorance respecting the nature of the round ligaments and their functions The experiments of Savage and others have shown that when the uterus is in a normal position, the round ligaments are relaxed and contribute nothing to its support The curved and somewhat tortuous course which they pursue from the cornua of the uterus between the folds of the broad ligament and around the bladder to the inguinal canals, gives them a slack of about two inches The conclusion from this fact that they perform no important office in the maintainance of the uterus in its normal position, is, however, erroneous The round ligaments are the only structures which are so related to the uterus as to make tension upon it from above The action of the lateral ligaments seem to be largely that of guys, by which the organ is so balanced that it may be kept in its proper place by the pressure of the contiguous organs, the bladder in front and the bowels behind Very little force is required to sink the uterus in the pelvis to the extent of two inches When a woman is coughing violently, straining at stool, or lifting heavy weights, the uterus is doubtless forced downwards in the pelvic cavity, and thus the round ligaments are brought into efficient action It

seems to me very clear that the chief function of the round ligaments is to prevent excessive downward displacement of the uterus from such causes as are very frequently, though temporarily, in action

The general lack of confidence in this operation has seemed to be based upon a belief that the round ligaments are not sufficiently strong to resist the strain to which they are subjected An experiment which I made for the purpose of testing the strength of the ligaments, may be of interest in this connection Having removed the outer four inches of two ligaments, I secured the two ends of one to silk ligatures While the ligament was suspended by one ligature, a weight was attached to the other, which was gradually increased to eight pounds and ten ounces, when the ligament broke, or rather was cut off by the ligature The stretching of the ligament during the experiment did not amount to more than one fourth inch When it is remembered that the portion of the ligament removed is its smallest and weakest part, and that the weight of the uterus is at most only a few ounces, it will at once appear that the relative and the absolute strength of these structures has been very greatly underrated A further consideration of much importance is that the ligaments are not expected to maintain perpetually the strain to which they are at first subjected In one of the accompanying cuts, (Fig 1), I have attempted to show the normal position of the uterus and its relations to the round ligaments and contiguous organs

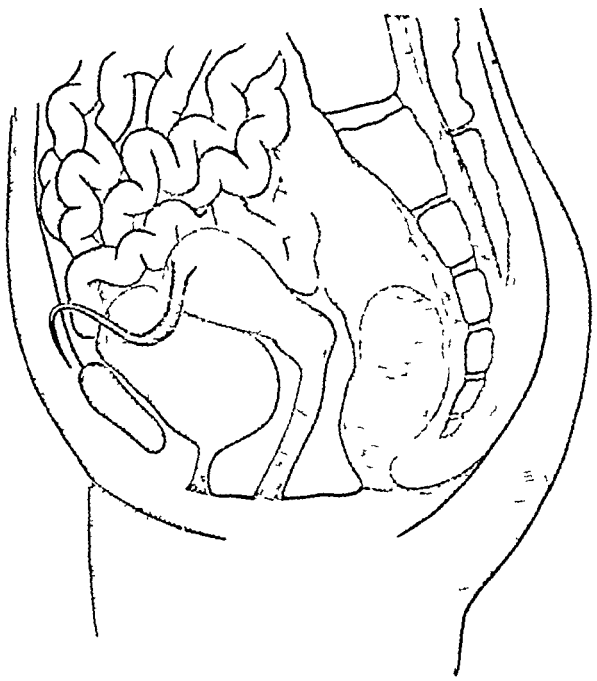

FIGURE 1

As will be seen by reference to the cut, the uterus, when in its normal position, lies forward, out of the line of downward action, and its wedge shaped body is buoyed up by the bladder in front and the inflated intestines behind When the uterus falls backward, it lies across the pelvis in such a way that it is directly in the line of downward action (Fig 2), the intestines enter the anterior cul de-sac, and the weight of the abdominal viscera is brought to bear in such a manner as continually to force the organ lower down In efforts to relieve the bowels, the contents of the colon impinge upon the upper side of the uterus in such a manner that the whole force of the effort to relieve the bowels is felt by the round ligaments, which are made taut and kept under continual strain When the ligaments are shortened by the performance of Alexander's operation, the uterus is rescued from its abnormal position and is brought back to the position shown in Fig 1 The intestines are made to retreat from the anterior cul de sac and assume their normal position behind the uterus When this has been accomplished, the normal forces

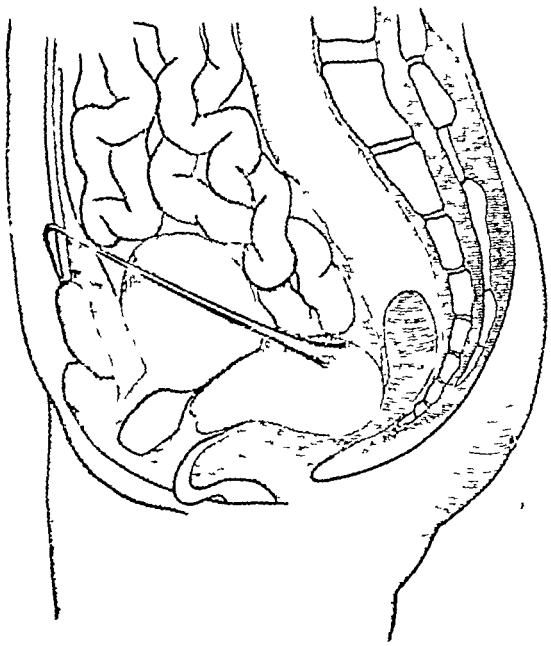

FIGURE 2

which sustain the organ come into play, and it is only expected of the round ligaments that, as Dr Alexander expressed it, they shall act as mooring ropes to hold the uterus forward, so that really only a very small amount of strain is brought upon them Their ability to do this has been amply demonstrated not only by the experiments referred to, in which I showed their tensile strength to be very great, but in the numerous cases of this operation in which they have satisfactorily performed the service expected of them Both analogy and the results of pathological investigation show that in some cases, at least, retrodisplacements and procidentia are due not solely to a stretching of the supporting ligaments, but to an hypertrophy or hyperplasia of these structures I have found positive proof of this fact in several cases of extreme retroversion of several years standing Instead of finding the round ligaments attenuated, as I expected, I found them extraordinarily large In two instances the ligaments were fully 18 mm in diameter By means of this operation, a process of involution is set up, and it is only required that the round ligaments shall hold the womb forward out of the "abdominal current," while this process is taking place, and the surrounding organs are readjusting

themselves in normal relations to the uterus Changes of this sort are sometimes secured by a suitably adjusted pessary, but by shortening the round ligaments, this end is much more efficiently and certainly attained

As regards the indications for the operation, I believe that it may be usefully and properly performed in the following classes of cases

1 Cases of procidentia in which the causes are chiefly such as operate from above, and in which the patient is not relieved by the operation of perineorrhaphy, when this operation is required I am not sure that the operation is applicable to women who are many years past the menopause, but in cases of this sort I have obtained very satisfactory results by means of the median colporrhaphy of LeFort

2 Cases of retroversion or retroflexion which are not cured by the employment of less heroic means

3 Cases of anteflexion combined with retroversion and prolapsus of the ovaries I see no reason why the operation should not be also employed for the relief of prolapsus of the ovaries alone I have now in hand a case of this sort which has resisted for years all other means of treatment, and upon which I intend to make a trial of the operation

4 Cases of anteversion where the fundus lies behind the pubis I believe the view of Thomas and some other gynecologists, that anteversion may be due to shortening of the round ligaments, is incorrect Indeed, I think I have proved this to be the case by relieving a case of extreme anteversion by the performance of Alexander's operation I have attempted to show in Fig 3 the relation of the

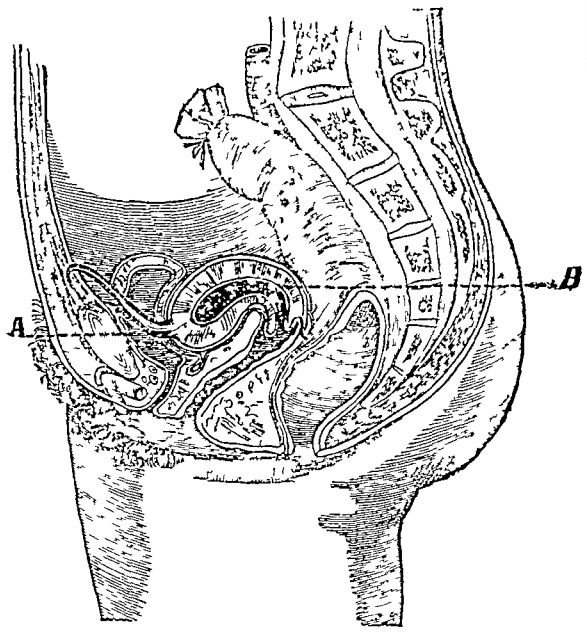

FIGURE 3

round ligament to the uterus in anteversion By a glance at the cut it is easy to see that anteversion cannot possibly occur as the result of shortening of the round ligaments I will remark further upon this point in reporting the case referred to

I do not wish to be understood as advocating that all cases of displacement, either prolapsus, retroversion, or inteversion, should be subjected to Alexander's operation I have long been convinced that many cases of displacement require no treatment at all, certainly no surgical operation The treatment of a displacement which gives rise to no symptoms, either local or remote, may, in my estimation, be properly termed meddlesome gynecology In many cases in which treatment is required, a cure may be effected by simple means, especially by the removal of such causes as improper dress, a chronic habit of constipation, or weakness of the abdominal muscles In all cases, whether this operation is resorted to or not, such means should be employed as will strengthen the abdominal muscles, restore the natural supports which may have been weakened, and build up the general health

The following is a report of all cases on which I have performed this operation up to date

Case 1 Mrs R , aged 24, suffering with complete procidentia The cervix uteri protruded fully two inches, and was lacerated to the os internum on both sides The patient suffered with very profuse menstruation, and was in a very feeble condition The same patient had been under my care in 1884, at which time I found the same conditions which had then existed for four years, the procidentia having begun before marriage At that time I performed trachelorrhaphy and anterior and posterior colporrhaphy, by which she was temporarily relieved In 1885 she again became pregnant, and at childbirth the cervix was again lacerated The procidentia returned as bad as ever, and existed for more than a year before I again saw the patient All sorts of pessaries had been tried without relief

I thought this case a suitable one for the trial of Alexander's operation, and after making some preliminary dissections on the cadaver, I operated, Oct 29, 1886, having repaired the laceration of the cervix a few weeks previous The ligaments were found to be very small, but both were found and drawn out four inches The ligaments were secured by deep silver sutures and superficial silk sutures A few small vessels were tied with cat gut Drainage tubes were placed at the lower end of the wound, and the uterus supported in position by dry cotton pledgets well dusted with powdered boracic acid The cotton support was changed every day, and a hot vaginal douche administered Drainage tube was removed on third day The right side healed readily, the left side more slowly Patient was discharged, and returned to her home Dec 31, 1886, in excellent health, with none of the former symptoms Uterus was held perfectly in position, without pessary of any sort Patient able to be on her feet all day without difficulty I heard from this patient several months later She was then engaged in business which required her to be upon her feet constantly Was wearing no pessary, and was pronounced by her family physician to be in perfect health At last accounts she was still well, with none of the old symptoms

Case 2 Miss L B , aged 25 At eighteen had a

severe fall from a carriage At next menstrual period had an epileptic convulsion Subject to frequent attacks of epilepsy ever since, and had suffered constant headache and backache Had been under the care of several physicians, who had employed pessaries and treatment of various sorts for the relief of retroversion On making examination, found retroversion and flexion, the fundus very low and nearly double normal size, ovaries enlarged and prolapsed Patient's general health was wretched Was emaciated, extremely nervous, depressed, and had tender spine, moist palms, and constant headache Was unable to wear any kind of pessary on account of pain caused by pressure on the ovaries, but when a properly adjusted pessary could be tolerated, had always found relief from the epilepsy, so long as the uterus was held in position For some years this had been accomplished by means of a pessary with an external support, but as this had become intolerable, it had to be abandoned Patient had used bromides freely for the relief of epilepsy, as the result of which there was decided hebetude, and very bad digestion The patient was altogether wretched

Operation March 3, 1887 Both cords were found well developed Shortened three and one-half inches Secured the ends with deep sutures, wire upon one side, cat-gut upon the other Placed drainage tube and applied iodoform dressing Placed stem pessary to hold the uterus in position Had to remove the pessary on third day on account of pain and epileptic convulsions which seemed to be induced by it Pain and convulsions ceased immediately upon its removal Wounds healed by first intention Highest temperature reached at any time, 100° F Patient discharged, April 18, relieved of backache and other nervous symptoms Was gaining rapidly in flesh The fundus uteri was held in good position, but the cervix was still flexed on account of the enforced premature removal of the stem pessary Recent reports showed great improvement in all particulars Great gain in flesh and strength No epilepsy

Case 3 Miss C B, aged 25 This patient came first under my care at the Sanitarium in October, 1885 At that time was so feeble that she had been bed-ridden most of the time for three years, and was unable to engage in any kind of labor Uterus was retroverted and prolapsed to the third degree Both ovaries were also prolapsed, enlarged, and tender Among other leading symptoms, were a highly sensitive spine, great nervous irritability, mental depression, palpitation of the heart, deranged digestion, extremely profuse and painful menstruation, usually lasting six days This patient had been under constant medical treatment for years Had consulted eminent and skillful physicians who had exhausted their skill in efforts to find some form of pessary which would afford relief, but without securing more than temporary benefit After six months treatment, which consisted chiefly of measures calculated to build up her general health and increase the tone of the muscular system, she returned home very greatly improved, but gradually drifted back into her old condition and returned, March 4, to see if anything could be done for her

Operation March 23 Both ligaments were found and shortened about four inches, and were secured in the wound in the usual manner Highest temperature registered was 100 2° F Wounds did not unite by first intention, which was due to sloughing of the outer ends of the ligaments, which were tucked in the wound instead of being cut off Patient left the surgical ward 24 days after the operation, being able to go to her meals in the general dining room in a wheel chair Up to the date of the present writing, the womb has remained in a slightly anteflexed position The ovaries, which were formerly very low, can not be discovered by digital examination The following is the patient's own description of her own condition before the operation and since

"I had suffered constantly for six years with severe pain in my head, back and pelvis Could not stand erect during these years on account of extreme soreness in the pelvis and abdomen During menstruation I was compelled to keep my bed for five or six days and in great agony Complete nervous prostration Could not be on my feet five minutes at any time without great discomfort My spine was so tender I could not bear the touch of clothing Almost continual palpitation of the heart Now, after having Alexander's operation performed, I am able to sit, ride, or walk, with ease The pain and soreness has disappeared from my spine as well as from the pelvis and abdomen My head is clear My heart is all right Instead of menstruating six days, the menstruation lasts but two days, with almost no pain, and I am able to be about during the time, which was utterly impossible before And last, but not least, my shattered nerves are fast recovering"

Case 4 Mrs M, aged 30 Retroversion and slight flexion, uterus lying very low in the hollow of the sacrum Patient complains of constant pain in the right thigh and through the right side of the body Both ovaries tender and prolapsed Vaginal and cervical catarrh Hypertrophy of cervix with induration Menstrual flow profuse, attended by much pain The patient's general health had suffered much She was very neurasthenic Complained much of inability to sleep Had been under excellent medical care for many years, but had steadily declined in health Had borne one child, since which time her troubles had been aggravated, but believed the retroversion was present before marriage, dating back ten years

Operation March 29 Uterus drawn forward as much as possible Ligaments shortened about four inches, and secured in the wound by cat gut sutures, the outer ends of the ligaments being tucked into the wound Highest temperature, 100 2° F, which was only reached a few times, and was due to the sloughing of the outer ends of the ligaments, by which union by first intention was prevented Wounds were somewhat slow in healing, but gave the patient little discomfort Menstruation occurred the second week following the operation The patient expressed herself as very comfortable No pain or inconvenience excepting retention of the urine, necessitating the use of the catheter a few times This I attributed to the pressure of the sup-

port by which the uterus was held in place rather than to the pressure of the womb, as relief was obtained when the cotton pledgets were removed The patient said she had not had so easy a time in many years Patient discharged from the ward April 27 Allowed to walk about the house Went home six weeks later relieved of all her old difficulties, and with the uterus in perfectly normal position Ovaries out of reach The patient was able to take vigorous exercise in the gymnasium and long walks without any inconvenience whatever Stronger than ever before in her life, sleeping well and in excellent spirits, wearing no pessary I was more than usually pleased with the results of this case, as the patient had been warned against the operation by her family physician, who, after a consultation with a professor of gynecology in a neighboring State, informed her that the operation was "difficult and dangerous," and not likely to secure any good results, but the failure of all other means to secure to her relief from her many sufferings, induced her to submit to the operation, and she was well satisfied with the results

Case 5 Mrs D, aged 28 *In good health until* birth of first child, nine years previous, when she "got up too soon" Constant, distressing pains in the ovaries, extending to the limbs Severe dysmenorrhœa Pain and tenderness the whole length of the spine Constant occipital headache Patient extremely nervous Confined to bed much of the time Found uterus retroverted and flexed Ovaries tender and prolapsed

Operation April 13 Ligaments shortened four inches, and secured by deep and superficial cat gut sutures The outer ends of the ligaments were tucked into the wound The second day following the operation the patient suffered considerably from swelling of the uterus about the wound and over the pubes, which extended into the labia of the right side Pain and swelling relieved by poulticing The patient had been accustomed to the administration of large doses of morphia whenever suffering pain, and received several doses of ⅛ to ¼ gr of morphia administered hypodermically The outer portion of the ligaments sloughed, and the wound healed slowly by granulation Highest temperature 102 3° F Patient went home on June 3 on her feet, and gaining rapidly in strength and flesh Uterus and ovaries were in normal position, menstrual period much less painful than formerly

Case 6 Mrs V, aged 30, suffered many years with backache and pelvic pains Severe pain at menstrual periods General and nervous debility, mental depression, dyspareunia, and disordered digestion

Operation, April 3 Ligament on right side was found well developed, but was firmly adherent to the internal ring, so that it could not be drawn forward Suspecting that this might be due to some anatomical peculiarity, I closed the wound in the usual way, and did not operate upon the left side Wound healed by first intention Highest temperature 100° F I have since regretted that I did not operate upon the left side, as in subsequent cases I have found a great variation in the condition of the ligaments of the two sides

Case 7 Mrs W, aged 42 The patient complained of constant pelvic pain, chiefly in the left side Greatest at night Much increased during menstrual period Also pain in the lumbar region, and continual bearing down pain Patient very feeble Unable to walk any distance or to perform household duties Very great nervous prostration and general weakness Physical examination showed extensive abrasion of the cervix with considerable hypertrophy and induration of the entire uterus The last physician who had examined the patient had pronounced the disease of the cervix to be malignant Great tenderness and throbbing all about the uterus

After a few weeks' preparatory treatment, Alexander's operation was performed on April 21 Both ligaments were found and shortened about four inches Ends of ligaments secured by cat gut sutures Wounds dressed in the usual manner Considerable swelling of the wounds which only partially healed by first intention Highest temperature 101 1° F, which was due to a small abscess which formed at the upper angle of the wound on the right side Patient left the ward May 17 Was allowed to walk May 26, with the uterus and ovaries in normal position No pelvic pain or tenderness No throbbing Uterus normal size No local symptom of any sort except slight vaginal catarrh Patient was instructed to continue the employment of the hot douche, massage, and general faradization under the care of a good nurse, and reports continued and very satisfactory improvement

Case 8 Miss L, aged 29 Had been out of health for five years For three years very miserable, and under constant medical care Severe and constant lumbar pains, occipital headache, and a great variety

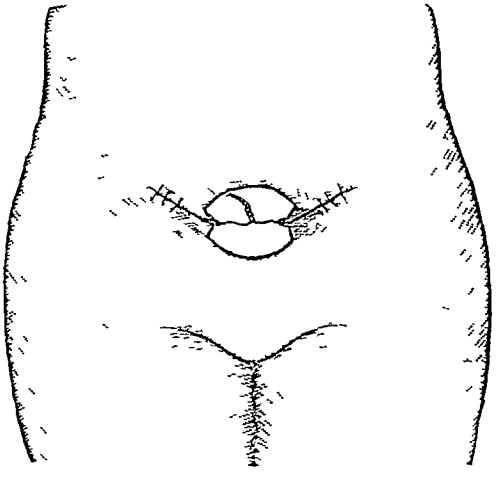

FIGURE 4

of neurasthenic symptoms Painful and profuse menstruation, dysmenorrhœa and severe menorrhagia Uterus found retroverted and slightly retroflexed, lying in the hollow of the sacrum Both ovaries prolapsed and tender Much tenderness and throbbing all about the uterus

Operation, April 24 Ligaments shortened about

four and one-half inches From observation in previous cases, I had come to the conclusion that failure to secure immediate union was in some cases due to traction of the ligaments upon the sutures To obviate this difficulty, I secured a silver wire to the end of each ligament, and twisted the ends of the wires together over a broad plate of hard rubber placed upon the pubes and between the lower angles of the wound, as shown in Fig 4 In other respects the wounds were closed in the usual way There was little or no swelling of the wounds, which healed by first intention Stitches removed one week after operation Later there was a slight discharge from the upper angle of each wound Highest temperature 99 9° F Four weeks after the operation patient was allowed to go upon her feet without other support than two small cotton pledgets At the present time, the patient is still under treatment for digestive disorders and nervous conditions, but the uterus is of normal size and in normal position, and patient has very few local symptoms of any sort The ovaries are out of reach, and apparently healthy

Case 9 Mrs M, aged 39 Had suffered with prolapsus and retroversion for fifteen years Had had good medical care, but found no relief, and for several years had been thoroughly broken down in health Suffered with all the symptoms which usually accompany the conditions named Upon examination, found the uterus retroverted and flexed, lying very low in the hollow of the sacrum Displacement easily reducible, but the organ would not remain in position

After a few weeks' preparatory treatment, I operated, April 20 Found ligaments exceedingly attenuated The right ligament was not more than 1½ lines in diameter The left was a mere filament, which broke in the attempt to secure it Shortened the right ligament five inches Secured it by two deep sutures of silver wire attached to lead buttons Wounds healed by first intention Ten days after the operation found the uterus partly retroverted, so that the fundus was felt in posterior cul de sac I feared the operation was a failure, as I observed that the posterior wall was closely adherent to the fundus, showing that adhesions were present which I had previously overlooked I think the oversight was due to the fact that the uterus was placed in position with perfect ease, which was made possible by the very relaxed condition of the vaginal walls Ten days later, on examination, found the uterus well anteverted, the fundus was easily felt in front, and could not be found behind The ovaries, which were previously within easy reach, could not be found From this time until June 3, when the patient returned to her home, the uterus remained in perfect position The patient was able to be about upon her feet as much as she chose, without support of any sort, yet the uterus showed no inclination toward prolapse or retroversion There was a notable decrease in the size of the organ, and the adhesion of the posterior wall to the fundus had disappeared This case was of great interest to me, as it demonstrated the ability of a single ligament, and that of very small size, to resist the strain not only of the weight of the uterus, but of the vaginal walls attached by adhesion, and ultimately to break the uterus loose from its attachments and restore it to a normal position The fact that the uterus remained so perfectly in position I attributed to the readjustment of the surrounding organs in their normal positions, and especially the return of the small intestines to their normal position behind the uterus When last seen, the patient was relieved of most of her former distressing symptoms, and was rapidly gaining in flesh and strength

Case 10 Miss H, aged 30, had been engaged as a teacher for many years Had suffered with constant weariness, severe pain in the lumbar region through the pelvis, and the general symptoms of nervous debility and obstinate constipation Physical examination showed retroversion and flexion, uterus lying low in the hollow of the sacrum, ovaries low and tender, also tenderness of the body of the uterus Patient had had much local treatment, was last under the treatment of an eminent specialist in St Louis, Mo All sorts of pessaries had been tried without benefit, and the patient had become a confirmed invalid

Operation, May 5 Both ligaments found and shortened about five inches Wounds healed by first intention, but afterwards opened slightly at the upper angles Highest temperature 100 1° F Patient left the ward 24 days after the operation, and has been steadily gaining since Is relieved of the lumbar and pelvic pain Bowels are regular Uterus and ovaries are in perfect position

Case 11 Mrs N, aged 47 Never pregnant The patient had suffered from complete procidentia and a great variety of local and general symptoms *for 11 years* Severe pain at menstrual period Eighteen months previously I had performed a posterior colporrhaphy by a modification of Simon's method, after which it was possible to hold the womb in position by means of a lever pessary Previous to this time the organ would not remain in position for five minutes when the patient was on her feet, without the aid of an inflated rubber ball The patient was very comfortable for a few months, when the pessary became displaced and began to give discomfort It was removed by her home physician, who did not succeed in again affording relief by the aid of a pessary She again consulted me March 23, 1887, when I found the condition as regards procidentia nearly as bad as before the operation

Operation performed May 9 Ligaments were small, and were not so much elongated as I expected to find them The uterus was drawn up as far as possible, but I was not able to shorten the ligaments more than 2½ inches Secured the ligaments over a rubber plate as in the preceding case, and closed the wound in the usual manner The left side healed by first intention The right side was not so fortunate The superficial portions of the wound healed by immediate union, but subsequently opened up and closed by granulation Highest temperature was 101°, which occurred eight days after the operation and was due to suppuration in the left wound Thus far the uterus remains in anteversion, and there is no sign of prolapsus, although before the operation the

prolapsus was constant, even when the patient was lying on her back

Case 12 Miss M , aged 33, has been an invalid for eight years, has been under medical care most of the time Very weak and nervous, unable to be upon her feet any length of time, and incapable of exercise of any sort Suffers with constant pain in pelvis, which is greatly increased at the menstrual periods, particularly in uterus and left ovary Profuse leucorrhœa Constant bearing down, and great distress in lower abdomen when on her feet On local examination found complete anteversion with anteflexion of first degree As all sorts of pessaries and other means of treatment had been employed without success, I determined to see what could be done for a case of this sort by Alexander's operation

Operation, May 31 Found both ligaments, which were rather small in size After freeing ligaments from their attachments, and before making traction upon them, I introduced one finger into the vagina and placed it upon the fundus of the uterus, which lay under the pubes, while the cervix was in the hollow of the sacrum With the finger of the right hand in this position, I made traction with my left hand upon the two ligaments simultaneously I felt the uterus dragged upward away from the finger of the right hand, it being lifted fully two inches upward and backward, where it was retained, the ligaments being secured over a rubber plate as in preceding cases The wounds were closed in the usual manner Since the operation the patient has been entirely relieved of the bearing down pain which she previously suffered more or less, even when lying in bed, although, of course, the result of the operation cannot be determined until she gets upon her feet

It seems to me that this case demonstrates not only the utility of Alexander's operation in cases of extreme anteversion, but also the erroneous character of the views which have heretofore been held by some gynecologists, in attributing anteversion to abnormal shortening of the round ligaments Thomas gives shortening of the round ligaments as one of the causes of anteversion, and in speaking of the changes which occur in the uterine ligaments in cases of anteversion, he further states "In anteversion the utero sacral ligaments are generally shortened, and there is no doubt that the round ligaments are similarly altered " The fact that the uterus was lifted bodily out of its abnormal position and drawn backward to its normal position by the round ligaments, and that it was found necessary to shorten the ligaments fully three inches, shows that anteversion as the result of abnormal shortness of the round ligaments is an utter impossibility It would also seem to demonstrate that shortening of the ligaments does not occur in anteversion—at least that a longer period than eight years is necessary even for the beginning of a change of this sort

It would seem that a consideration of the anatomical relations of the round ligaments, the internal abdominal ring and the uterus, would be a sufficient demonstration of the ability of the ligaments to raise the womb to its normal position and the impossibility of anteversion occurring as the result of shortening of the ligaments The point at which the round ligaments enter the inguinal canal is halfway between the spine and pubes, and the anterior superior spine of the crest of the ilium is opposite the middle of Poupart's ligament, so that, with the uterus in anteversion, the action of the ligaments is calculated to restrain the organ from extreme anteversion I am inclined to the belief that extreme anteversion cannot occur without elongation of the ligaments

[Since this paper was written, the patient has left the surgical ward, and has now been upon her feet for several weeks The uterus remains in perfect position, and she is quite relieved of the distressing "bearing down" of which she previously suffered I feared that when the patient should get upon her feet, the uterus would rapidly return to its old position under the pubes, but, to my surprise, the fundus has been steadily retreating from a half anteverted position until, at the present date, August 1, the uterus is in a position which would be perfectly normal were it not for the fact that the slight anteflexion which existed still remains It is necessary to introduce the finger to its full length in order to be able to reach the fundus]

THE RELATION BETWEEN ERYSIPELAS AND PUERPERAL FEVER, CONSIDERING ERYSIPELAS BOTH AS AN ACUTE AND A LATENT DISEASE

Read before the Section on Obstetrics and Gynecology, at the Thirty eighth Annual Meeting of the American Medical Association held at Chicago, June, 1887

BY A MACLAREN, M D,
OF ST PAUL MINN

Before proceeding to the discussion of this subject let me present to you, in as concise a form as possible, my definition for the term puerperal fever It is *not* a specific fever, as Dr F Barker would have us believe, but a disease due to the absorption, by a puerperal patient of some septic poison, this poison being absorbed either by the lymphatics or the veins at the site of some breach of continuity in the parturient canal It is then, in short, nothing more or less than septic fever, showing the same pathological changes and giving the same clinical symptoms as are seen in different surgical patients who have suffered from septic infection

In the year 1886 there were published two particularly valuable works on the subject of Obstetrics The first of these, Cazeau and Tarnier's "Theory and Practice of Obstetrics," with its 1,200 pages, does not make the slightest reference to the relation existing between Erysipelas and Puerperal Fever In Dr Mundé's appendix, however, there is this note bearing upon the subject "That the exanthemata cause puerperal fever I do not believe, for while after labor the material organism has lessened power to oppose the approach of disease, and is less able to withstand its inroads, scarlatina or other exanthem, when it appears at this time, still preserves its distinctive characteristics, though perhaps running an

unusually malignant course, yet we cannot call it puerperal fever" As Dr Mundé makes no mention of erysipelas, I understand that he here includes it with the exanthemata

The second work to which I refer is Dr Lusk's "Science and Art of Midwifery" There we find a very exhaustive *resume* of all the latest theories and investigations as to the nature and causation of puerperal fever, which Professor Lusk sums up in these words "Thus we find in surgical fever, in puerperal fever, in diphtheria and in erysipelas, the presence of a common element which links them together, and which establishes the relationship which has so long been recognized as existing between these various processes"

This connecting link of which Dr Lusk speaks is the chain-like micrococci which up to the present time have resisted all efforts at differentiation Among the workers and authorities in this field, he quotes such men as Koch, Lukomski, Dolčris, Samuel and Virchow, the last named author upholding this theory of bacterial origin in these words, "Especially in this connection are to be mentioned the *diphtheritic* process and the *erysipelatous*, especially erysipelas malignum The granular deposit in diphtheritically affected tissues, of which I formerly spoke, has more and more proved to be of a parasitic character" I have as you will see simply reiterated Dr Lusk's arguments and for two reasons, 1 I do not feel myself competent to discuss the bacterial element of the disease, and, 2 I whish to show the wide difference of opinion between the two schools as shown by these two eminent teachers, differences which would lead them widely apart in the treatment of puerperal fever and especially in the prophylactic treatment of the disease

Before leaving this part of my subject let me call your attention to Dr Joseph Kucher's work on "Puerperal Convalescence" Dr Kucher takes the position that Semmelweiss' theory for the causation of puerperal fever is the only true standard, and that the septic poison which produced the disease is probably the chain-like micrococcus In several places Dr Kucher takes the position that the poison of erysipelas can produce puerperal fever, mentioning cases to prove his position which I shall refer to later

There are many surgeons who contend that erysipelas is essentially a skin disease, with more or less severe constitional symptoms, and that we must have the skin eruption or else the disease cannot be erysipelatous in nature In Holmes' "System of Surgery," we find this sentence "It has been objected by Sir W Lawrence, who in this supports the views of Vogel and Hildenbrand, that to justify the notion of the mucous and serous membranes being affected by erysipelas, it must be shown that the same phenomena are observable in them as are seen in the skin" Holmes answers these objections in these words "Besides diffuse cellular inflammation, there are many diseases which do not produce the characteristic cutaneous inflammation of erysipelas, yet are *probably* closely allied to it, as e g, *phlebitis*, both external and internal, *inflamed absorbents* and puerperal fever The same may be said of some forms of inflammation of the mucous and serous membranes For though the inflammation of the skin is absent, yet if the constitutional conditions be the same, they must be regarded as pathologically identical with erysipelas, however the expression of the condition may differ, just as in *syphilis*, the same virus may produce simple chancre or phagedenic sore, or various forms of cutaneous diseases, or deep seated inflammation" The clinical fact that a puerperal woman my have a localized erysipelas of the skin in some part of the body, and *not* have puerperal fever is to my mind no *proof* that erysipelas cannot *cause* puerperal fever It is simply the woman's good fortune, for if the bacillus had been planted in the parturient canal instead of on the skin, the woman would have suffered from child bed fever instead of the much less dangerous skin disease

Allow me to offer in support of this theory a few cases in which the poison which produced the attack of puerperal fever seems to have been directly referable to an acute attack of erysipelas of the skin, and *not* due to the poison of another puerperal case

Case 1 Some years ago Dr A J Stone, of St Paul, was called to take the case of Mrs R, who was just starting in confinement *Mrs Dr Stone* had been ill for the preceeding 24 hours suffering with pain in the *back*, *face* and eyes, with rise of both temperature and pulse Wednesday morning Dr Stone delivered Mrs R, the labor being normal, O A position, with no apparent injury to the parturient canal Thursday Mrs R had a mild chill, but with no rise in temperature, accompanied however by profuse sweating Had severe pains in back, side and head, and considerable nausea Friday, another chill, but still no rise in temperature Saturday severe chill followed by temperature of 105°, and on this day the lochia for the first time became scant and very offensive Intra uterine injections given regularly every every two or three hours for the next six days, and on the 10th day after delivery the temperature became normal and patient went on to a complete recovery At this time there was *no* puerperal fever in St Paul, and neither Dr Stone nor his nurse had seen a case of this disease for over a year Dr Stone gave up the rest of his practice for the time, and attended solely to these two patients, Mrs R and his wife He now feels that the attack of puerperal fever was simply puerperal erysipelas carried directly from Mrs Stone to his patient Mrs B

Case 2 —I was called in consultation to see a case of puerperal fever by Dr M, of St Paul, who prefers to withhold his name Dr M was attending a case of facial erysipelas when called on March 4th to deliver Mrs D, of St Paul Labor normal, O A position 48 hours after delivery Mrs D had a severe chill with a temperature immediately afterwards of 105° F, pulse 120 Chill every day Lochia suppressed and rather offensive When I saw the patient she was suffering from a well marked case of puerperal pyæmia Examination showed slight tear of the perineum, lochia very scant and offensive Temperature 103 5° F, pulse 130 Patient died on the 16th of March, having developed metastatic abscesses in left ankle and in lungs The nurse had

not attended a case of puerperal fever for over a year Dr M had not seen a case of puerperal trouble for over six months, and both had attended any number of confinement cases in the meantime, all of whom had recovered without a single septic symptom

Dr Ambrose Guichard reports a case bearing directly upon this subject in the *Archives de Tocologie*, July, 1885 Mrs D at 27, delivered for the 4th time, Jan 17, 1885 Labor normal but rapid Jan 20th, patient had a chill, fever, diarrhœa, tenderness of abdomen, suppression of lochia, and became delirious Despite antiphlogistic treatment and intra uterine douches, patient died on Jan 30th of general puerperal peritonitis The husband of this woman, who occupied the same bed at night, had facial erysipelas when first seen by Dr Guichard, eruption having developed three days before the delivery of his wife The midwife who saw Mrs D immediately after delivery made no examination and had not been in any way exposed to puerperal fever

Dr Kucher makes the following quotation from Tyler Smith "In another case a medical man was in constant attendance upon a patient suffering from gangrenous erysipelas, and between Jan 8th and Mar 22d he attended the labors of ten women, all had puerperal fever, and eight of the patients died " This was in a town of moderate size, no other practitioners in the place were known to have had cases of puerperal fever Several hundred similar cases are recorded

Thus far in my review of this subject I have simply gone over the ground which has been so often argued *pro* and *con* throughout the medical world during the past few years Now let me ask your attention to another phase of this subject If the bacterial origin of erysipelas be *true*, *why is it* that certain persons seem predisposed to innumerable attacks of this disease? We have all seen many subjects in whom a slight indisposition brought on an acute attack of erysipelas and almost *always* located in the same area of skin surface, and these attacks *without* apparent exposure Is not the answer to my question, that the first attack of erysipelas has never been *cured* and that the bacillus still *lives* in the skin ready to break out into a fresh attack upon the slightest provocation? It seems to me that this must be the answer, *for*, the cases of predisposition, of which every text-book speaks, and which we have all seen, are too numerous to allow of the *supposition* that each one of them has been repoisoned If you grant me this then you must agree with me in the belief that a person who has suffered from an attack of erysipelas, and in whom the disease is dormant, or never has been cured, can communicate the disease to *an open* wound or to a puerperal woman

I have among my records a few surgical cases which seem to allow of such an explanation

Case 1 —Mr W , operated upon at St Joseph's Hospital Dec 7, 1886, by Dr C A Wheaton, of St Paul, for the removal of a large sarcomatous growth of the right thigh Every antiseptic precaution was used both during and after the operation Four days after the operation the patient had a chill, rise in temperature and developed erysipelas upon the leg, starting from the lower angle of the wound There was no erysipelas in the hospital, nor in the practice of Dr Wheaton or myself The nurse, however, one of the *best* and cleanest nurses whom I have ever met, had suffered with facial erysipelas some few months previous, she has shown no signs of erysipelas since, but I have *no* doubt that she still has the microbe of erysipelas living in her face or scalp

Case 2 —Oct 4, 1886, Miss B , operated upon by Dr Millard, of Stillwater, Minn , at St Joseph's Hospital, St Paul, for the removal of a 40 lb congenital perineal tumor diagnosticated to be *fœtus in fœtu*. The operation was performed in the new wing of the Hospital which had just been finished She was placed in a room never before occupied, with new bed and bedding, no erysipelas being then present in any part of the Hospital The patient was placed under the care of the same nurse of whom I have just spoken This nurse had been performing the executive duties of the hospital for several preceding months, and was only placed upon duty on account of the enlargement of the service and the scarcity of assistants The patient did remarkably well until the evening of the sixth day, when she had a severe chill The next succeeding day she developed erysipelas in the wound, which spread from there to the buttock and thigh of the right side She passed into a septic condition, from which she died on the 35th day, her physical condition corresponding very closely to that of a fatal case of puerperal septicæmia

Case 3 —Occurred at the same time on the person of a young lady upon whom Dr Wheaton had performed an Alexander's operation, and who was under the care of this same nurse, the wound upon the left side, which was almost entirely closed, seeming to be the starting point for the eruption which spread to the labia and inside of the thigh on the left leg There was no erysipelas in the Hospital nor in the practice of any of the physicians who were connected with either of these cases I have called the attention of both Dr Millard and Dr Wheaton to this theory for the causation of these cases of erysipelas, and they have both agreed with me in the strong probability, at least, of the truth of my explanation In looking back it seems that ever since the attack of facial erysipelas in this nurse, now over three years ago, ever since that time erysipelas has followed her, affecting apparently without cause her surgical patients Through the kindness of Dr Beal, of St Paul, I am able to present a number of puerperal cases which come in the direct line of argument

Dr Beal suffered from a very severe attack of facial erysipelas in the winter of 1885 In October, 1885, Dr Beal delivered Mrs G of her first child. Breech presentation I saw Mrs G , in consultation with Dr Beal, and applied forceps to the after coming head The labor was normal in every respect After examination showed laceration of cervix on the right side On the third day Mrs G had a very severe chill, followed by a rise in temperature, vomiting, pain in the back, head, and abdomen, with suppression of lochia Regular intra uterine injections and

a stimulating treatment were instituted but Mrs G died 16 days after delivery of puerperal septicæmia I never saw Mrs G after the night of her confinement, there was no other case of puerperal septicæmia in St Paul, so far as I could determine at that time, and I had not seen in the meantime a single case of scarlet fever, diphtheria or erysipelas, still my next case of confinement developed puerperal septicæmia on the third day after delivery

Mrs O, æt 21, primipara Delivered Nov 8, 1885 Labor tedious, head would not engage 36 hours after the commencement of labor she was placed thoroughly under the influence of chloroform, forceps applied and the head brought well down onto the perineum She was then allowed to deliver herself Female child weighing 9 lbs Slight tear of fourchette, not more than ¼ in in depth One hour after delivery, placenta not having come away after a thorough trial of Crede's method of expression and the patient being exsanguinated, the hand was thoroughly cleansed in bi chloride mercury solution 1 1000, and introduced into the vagina Two fingers were introduced into the uterus and the adherent placenta removed On the 3d day after delivery this patient developed a true case of puerperal pyæmia Intra uterine douches and stimulant treatment were of no avail, and she died suddenly on the 15th day from cerebral embolism The fact that it was found necessary to introduce the hand into the uterine cavity in this case, will probably be sufficient explanation to many of my hearers for this attack of puerperal fever, but still there seems to be a strong relationship between these two cases The same forceps used in Dr Beal's case were used in this case Out of 55 cases upon my obstetric records this is the only one whom I have delivered who has had the slightest septic trouble In several of my cases just as serious operative proceedings have been found necessary, and in several the hand has been introduced into the uterine cavity

In the spring of 1886 Dr Beal had a succession of puerperal fever cases The poison seeming to follow him so closely that he had at last to refuse to take any obstetric work As he expresses it, "Every woman that I saw during that last three weeks had a chill on the third day whether I touched her or not" During all this time Dr Beal used the most thorough and systematic antiseptic precautions bi chloride of mercury, baths, changing of clothes, use of nail brush and constant rinsing of the hands, but notwithstanding all this, nearly every woman had more or less puerperal trouble, with three fatal results

Mrs B, delivered April 2 O A position Forceps delivery The perineum was lacerated and was restored 5 hours after delivery by Drs Ritchie and Beal This patient had no trouble until the 9th day, when she had a severe chill, followed by a high temperature, pain in the back, head und abdomen Her child died in convulsions on this same day The patient had a chill every day until the 16th, when she died of puerperal septicæmia

Dr Beal's next case was Mrs H, who was in the 7th month of pregnancy Mrs H nearly aborted at the 5th month Her labor was normal Upon the 2d day after delivery Mrs H had a very severe chill followed by a temperature of 105 F, pulse small and rapid Lochia became scant, but not very offensive Suffered from pain in abdomen and back, very tender on pressure all about the uterus 3d day, chill followed by temperature of 105° 4th day, chill in the morning, temperature kept rising all day until evening, when she died of puerperal peritonitis, intra uterine douches having no effect whatever

About this time Dr Beal delivered Mrs T at full term, normal delivery, O A position On the 4th day she was found to have temperature 102° F, no chill Pain in the abdomen, was tympanitic and nauseated Suffered with a profuse diarrhœa Lochia became scant but not very offensive Until the 8th day patient slowly lost ground Temperature ranging between 102° in the morning and 103 5° in the evening Pulse high all the time On the 8th day the patient discontinued all medicine at the suggestion of a midwife, and Dr Beal did not see her again A physician who was called just before she died (on the 14th day) diagnosticated puerperal pyæmia, finding abscess in knee and in the apex of one lung

Besides these three fatal cases Dr Beal had several other patients about the same time and just before he gave up taking confinement casee, who suffered from mild puerperal attacks They had suppression of milk and decrease of lochia with rise in temperature, preceeded generally by a slight chill, all of these cases, probably 8 in number, recovered Every obstetric case occurring in Dr Beal's practice during this period had more or less trouble, excepting those cases which he delivered in the country Whether by chance or not every case in which he had to take a drive into the country went through confinement without any trouble After May, 1886 Dr Beal refused to take any confinement cases for the space of nearly a year At the end of that time he again commenced taking obstetric work, using every antiseptic care, but only to have another case of puerperal fever

There are several points of particular interest in all these puerperal cases The lochia, although suppressed, was not as offensive as in the majority of puerperal fever cases Intra uterine douches did not wash away as much detritus, shreds, clots, etc, as is usual The long drive in the open air seems to have been the means of preventing septic trouble in some of Dr Beal's cases

In conclusion let me review the main points of my argument briefly, presenting again my theory of latent erysipelas

1 Several of the latest investigators in the field of bacteriology claim that the poison of erysipelas surgical fever, and puerperal septicæmia or pyæmia is one and the same, and that they are to a certain extent interchangeable That when the poison from any one of these diseases is placed in the paturient canal at the time of labor, it will produce a train of symptoms which have been until lately classed together under one heading, i e, Puerperal Fever

2 Erysipelas being a disease due to a bacterial poison with a tendency to recurrent attacks without a second exposure, consequently the bacteria must

be able to live in the apparently healthy skin for an indefinite space of time

3 That the germs of erysipelas when living in this quiescent or dormant state, although they may not be able to excite an attack of erysipelas of the skin, may still under proper conditions produce either surgical or puerperal fever

In the first part of my paper I have presented a few cases on one side of a still unsettled subject In the last part I have offered a theory the truth or error of which time and careful investigation alone can prove

If my words may only cause a little greater care and the consequent saving of one material life I shall feel that I am more than repaid

A NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA OF THE SKIN

Read in the Section on Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY HENRY J REYNOLDS, M D ,

PROFESSOR OF DERMATOLOGY COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO PROFESSOR OF SKIN AND GENITO URINARY DISEASES, CHICAGO POLICLINIC ETC ETC

Various means have been adopted for producing local anæsthesia of the skin, but heretofore none has been to any extent a success Even cocaine, useful in most other tissues as a topical application, has absolutely no practical use as a local anæsthetic for the skin Though local anæthesia of the deeper parts may also be produced by the method which I am about to describe, I am only prepared to speak of its merits from a dermatological standpoint at present, but am nevertheless satified that the tissues can in this way be anæsthetized to a sufficient depth to render the method applicable in many cases to general surgery

As cocaine is the anæsthetizing agent, the method therefore relates only to the manner in which the drug is applied and its absoption induced Electricity is the means employed for this purpose Knowing that solutions of cocaine were not readily absorbed by the skin, and therefore produce no anæsthetic effect, Dr Wagner, of Vienna, about a year ago made experiments, the results of which he afterwards (*Wien med Blatt*, 1886, vol 9, p 161) presented to the Society of Physicians of Vienna in the form of a paper on that subject, with a view to ascertaining a more successful method of producing anæsthesia of the skin with this drug He found that by saturating the positive electrode of a galvanic battery with a solution of cocaine, applying it to the skin and then applying the negative electrode a short distance from the positive, with a moderate current on, that successful anæsthesia could be produced Since the publication of this article, though personally, as a rule, very skeptical regarding therapeutic innovations, I have been induced to make a number of experiments with the method, and to make frequent use of it in dermatological practice with quite a degree of satisfaction, and inasmuch therefore as I have in looking up the literature of the subject been unable to find any article touching upon the details or results of any personal experience with the method in this country, I feel justified in writing this article, in the hope that it may elicit discussion and the personal experience of others, and be the means of bring to the more general notice of the profession of this country a procedure which I deem of much importance in medical and surgical practice So far as I am aware, in fact, no article on the subject has appeared in medical literature other than the one just referred to With this apology, and without going into the details of my experiments, I trust that a brief description of the method and the results of my experience with it will be tolerated

Battery, strength of current, etc —I have used an eighteen cell McIntosh battery, but I think, in some cases, even a stronger current is necessary For reasons not necessary to discuss at present the Faradic current will not answer, neither will the negative pole of the galvanic The strength of the current must vary with the sensitiveness of the part, the size of the electrode, etc It is always necessary to use strongest current that can be borne, which may vary all the way from four or five cells (of the McIntosh battery) to twenty four, but for which no rule can be laid down, the only guide being the feelings of the patient and the experience and discretion of the physician Where the skin is very dense, the part not sensitive to electricity, and the electrode large owing to the greater surface necessary to be acted upon, (which thereby renders the current more diffused, and hence in a sense not so strong) the current must be very strong, requiring perhaps 24 cells of the McIntosh instrument The sponge on the electrode used for the solution should be of the finest and softest quality When a strong current is used the irritation at the negative pole may be avoided by using a larger electrode

Strength of solution —In my experience the cocaine should not be used weaker than a five per cent solution It may vary, however, owing to circumstances, from a two to a twenty per cent strength Where the skin is thin and the part such as will tolerate a strong current, a two to five per cent solution will answer On the other hand, if the part be so sensitive that only a weak current can be employed, as in portions of the face, the solution to be effectual must not be less than a ten per cent one

Mode of Application —Saturate the positive electrode with the solution and place it directly upon the part to be anæsthetized Place the negative electrode well saturated with water on some point near by A more remote point, as the hand of the opposite side, for instance, will answer, but it will take longer time and a stronger solution to get the effect than when placed near by In working about the face I think it is better to hold the negative electrode in the hand than to apply it to the face near the positive, as in this way a stronger current will be better tolerated

It is well for the operator to familiarize himself with the method by experiments upon his own person The electrodes should be kept firmly pressed

to the skin, the positive being now and then moistened as required with more of the solution, and the negative with more water If the negative produce much irritation it may be occasionally shifted to another place

Time Required to Produce Anæsthesia —This depends of course upon the location, the strength of the solution, the strength of the current, etc In the skin of the flexor surface of the forearm, if the negative pole be applied near by, a five per cent solution with about ten cells, say, of a McIntosh battery in good order, will produce profound anæsthesia in five minutes If the negative pole be placed in the hand of the opposite side about double that length of time will be required Whenever the skin is dense a longer time, stronger solution, and stronger current are necessary In any case, the current should be allowed to run as described till anæsthesia is produced, as ascertained by gently pricking now and then with some sharp instrument

Duration of Anæsthesia —This of course varies more or less also with the circumstances, as a rule however, the effect is rather transitory, lasting perhaps from five to fifteen minutes

Results in Practice —In the operation for the removal of superfluous hairs from the face by electrolysis, I have frequently used it In this operation, inasmuch as the tissues still conduct the current, an ordinary electrical sensation is experienced by the patient, but the sharp stinging, burning pain at the site of the needle, sometimes so acutely felt, is when the method is judiciously employed, entirely done away with In the removal of small warts, nævi, etc , from the face by the knife, it is even more satisfactory One obstacle in the way of its successful employment in certain portions of the face is the extreme sensitiveness of the part, owing to which condition a sufficiently strong current can not always be tolerated to induce the necessary absorption of the drug In a case of felon of the palm at the junction of the middle finger, I made a very careful effort with a ten per cent solution and sixteen cells of a McIntosh battery, to produce anæsthesia previous to lancing In this case the method as I employed it was not a success Failure in this case would be obvious for the following reasons *First*, the skin was very thick and callous, *second*, owing to the extreme soreness, not sufficient pressure with the electrode could be made to get the full benefit of the current, *third*, I think under the circumstances the current was not nearly as strong as it should have been In dental surgery I think the method can also be used to advantage I applied it in one case for Dr W H Gale, of this city, the patient was a lady for whom two teeth were extracted It is, of course, impossible to determine in such a case exactly how much benefit is desired from the procedure, but as nearly as could be ascertained, the pain in this case from the extraction was comparatively insignificant Ten cells of the McIntosh battery were used with a ten per cent solution

From the foregoing it will be seen that while under favorable circumstances complete anæsthesia of the skin may be in this way produced, like everything else, with our present knowledge of the method, it is not under all circumstances all that could be desired Notwithstanding, it has unquestionably, sufficient merit to warrant its recommendation to the profession and its general adoption by those in dermatological practice especially, and I am satisfied that with further experience, more, extended observation, improved appliances, and the more general adoption of the method, many of these apparent obstacles may be overcome

In conclusion I may summarize as follows

1 Complete anæsthesia of the skin may, under the proper conditions, be produced by cocaine applied in conjunction with the galvanic current

2 In dermatological practice, the method, which, for want of a better name, I may term "cocaine galvanism, galvano cocainism or galvano cocaine anæsthesia" is the best means for the purpose at our command

3 In dermatological practice, it is preferable to the hypodermic injection of the drug inasmuch as it is painless and frequently more effectual

4 The cocaine should not be used in less than a five per cent solution

5 The current should be as strong as the idiosyncracy of the patient and the sensitiveness of the part will permit

6 It is advisable in becoming familiar with its use for the physician to make some experiments upon his own person

7 All things considered, I think the method should be commended for general adoption in minor operations by those in dermatological practice

163 State Street, Chicago

DISCUSSION

DR SMITH, of Iowa, had used a hypodermic injection in removal of tumors

DR G W MCCASKEY, of Indiana Hypodermic injection can be used in surgical cases but is not necessary in all cases We cannot give electricity as accurately as we can cocaine Chloroform has been similarly used, but sometimes leaves an eschar Neuralgia of an intractable form has been cured by a hypodermic injection

DR FRANK R FRY, of St Louis I have experimented in applying cocaine I get best results by first washing the skin, and sponge well I do not use a sponge electrode but a small pad of muslin After using a small electrode I was led to use a large lead one, made in the shape of a band around the arm, protected by the muslin pad I put a pad of absorbent cotton soaked in a solution of cocaine, 10 per cent , for the negative electrode I have vesicated the skin previously Some patients can bear more than others

DR H N MOYER, of Chicago The action of cocaine is most resisted in superficial layers of epidermis We should use some neutral salt with cocaine, as we wish to aid passage of the cocaine through the animal membrane

DR H J REYNOLDS, of Chicago I did not mean that hypodermic injections were more useful than this method in superficial operations As a local

anæsthetic topically cocaine is not so useful Sebaceous matter may prevent absorption, hence we may use an alkaline wash The galvanometer is imperfect If we use a large electrode the current is diffused We do not use very powerful currents in this affection Where the skin is very sensitive the amount cannot do much damage, and the feelings of the patient are sometimes a good guide

DR M R CRANE, of Vermont I have scraped off the scarf skin and had good effects with 8 or 10 per cent solution of cocaine Patients do not object to this scraping The same size of electrode causes different effects upon different persons

AN UNAVOIDABLE DEFORMITY AND DISABILITY WHICH FOLLOWS CERTAIN CASES OF OUTWARD DISLOCATION OF THE FOOT

Read in the Section on Surgery at the Thirty Seventh Annual Meeting of the American Medical Association, June, 1887

BY E A WOOD, M D,

OF PITTSBURGH PA.

The dislocation outward of the foot at the ankle-joint is, in certain cases, followed by deformity and disability defined as follows Enlargement of the distal end of the tibia, increased prominence of the internal malleolus, increased malleolar space, turning of the foot outward, the axis of the foot presenting outside the axis of the leg, tenderness in and about the joint, pain when weight is borne on the foot, and inability to walk unaided

The difficulty is often attributed to "weakness," to incomplete reduction of the luxation, to too early exercise, to neglect or ignorance on the part of the surgeon, to neglect or carelessness on the part of the patient The blame is not always placed where it rightly belongs, and that this may be done hereafter is the object of this paper

If the nature of the trouble is not comprehended the patient will lay the blame on the surgeon, while the latter must feel embarrassed with doubts No more annoying dilemma can be conceived of in the practice of surgery, than where the surgeon cannot explain nor the patient comprehend the true character of a deformity and disability like the one under consideration Ignorance on one side or the other is always the cause of suits for malpractice

I have never known the deformity to exist except in cases of outward dislocations of the foot at the ankle joint In simple dislocation of the foot outward, the foot is rolled outward, and carried outside the axial line of the leg, carrying with it the external malleolus, the tibio tarsal ligaments are completely ruptured, and the external malleolus forms a tumor which may touch the floor should weight be borne on the injured limb

This, briefly, is the common dislocation, which is readily reduced, easily kept in place by suitable dressings, and which recovers without deformity or disability But suppose we have this simple luxation *plus* something more, suppose a person of heavy weight falls from a considerable height with such force as not only to dislocate the foot outward, but also to drive the end of the tibia against the ground or floor, where it receives all the weight of the body and the impetus of the fall, then it is obvious that we have something more serious than a dislocation That something more serious will be an injury to the distal end of the tibia in the shape of a severe contusion, or a split in the bone, or an impacted fracture, or all combined The tissues of the tibia and its articular surface will be severely injured

But in a case like the one presented the luxation is the most apparent, as it is the all absorbing lesion, the displacement is readily reduced, or perhaps it was reduced before the arrival of the surgeon who is to treat the case, and the most serious injury, the injured tibia, is lost sight of The dislocation is patent, the injury to tibia obscure The foot is out of place, there is no alteration in the outline of the tibia, and all pain and shock is attributed to the wounded ankle joint There is no trouble in reducing the dislocation or in keeping the parts *in situ*

In the case under consideration it is not the dislocation, but the obscure injury of the tibia, that is the cause of the subsequent deformity and disability An uncomplicated outward dislocation of the foot, if fairly treated, will get well in a reasonable time, and get well without deformity or disability, a severely injured tibia will likely result in inflammation with its consequences, as thickening of the periosteum, interosseous deposit, thickening of the articular cartilage, hypertrophy

In outward dislocations of the foot complicated with severe wounding of the distal end of the tibia, there will likely follow inflammation and enlargement of the part inflamed This enlargement will be not only circumferential, but longitudinal as well Bear in mind that, while the ruptured tibio tarsal ligaments offer no resistance to the encroachment of the elongated tibia on the joint space, thus shoving the astragalus before it, on the other side the fibulo tarsal ligaments, by being intact, firmly prevent the outer side of the foot from receding The result of these two opposing forces—the elongated tibia and the intact external lateral ligaments—will be the rolling of the foot outward

Another cause of the deformity is the enlargement of the circumference of the tibia, by which the intermalleolar space is increased Now, as the fibulo tarsal attachment is firm, while the tibio tarsal is loose, the foot will be carried along with the lower end of the fibula outside the axis of the leg The astragalus cannot fill the abnormally widened intermalleolar space, and, being firmly attached to the fibula, it must cling closely to that bone, and leave a space between the internal articular facet of the astragalus and its articular surface on the internal malleolus Besides, the thickened articular cartilage of the tibia will have changed the plane of the joint

Can the deformity be prevented? It is not a question pertaining to the dislocation, but one relating to an injured tibia, then, can the enlargement of the tibia be prevented? Whatever of uncertainty there may be in regard to the question of prevention, it is certain that timely and protracted treatment is nec-

essary, and that by such treatment we confine the deformity to its minimum

Let us take for consideration a case of outward dislocation of the foot complicated with severe injury of the end of the tibia Let us suppose that it is at the end of the third or fourth week No trouble was had in reducing the luxation nor in keeping it in place There was no manifestation of the latent mischief, except more pain and feverishness than usually attend simple dislocations But at the end of three or four weeks the surgeon, on removing the dressings, notices that the internal malleolus is more prominent than it should be, that the foot inclines to roll outward, and that the foot is slightly outside the axis of the leg He may also notice that the ankle is more swollen, tender and painful than usual in ankle dislocations These features, however, are but slight, and unnoticed by the patient, and indicative of a tendency to rather than actual deformity The surgeon is apt to attribute them to faulty dressings, and accordingly he adjusts these to overcome the slight deformity or tendency to deformity At the next dressing the surgeon learns that he has not succeeded, that the trouble persists, or is even increased, and he again adjusts the dressings to overcome the trouble, but weeks roll round and the deformity becomes more pronounced If the surgeon be a keen observer he will have learned by this time why the trouble persists, he will have discovered that the lower end of the tibia has enlarged, and that the intermalleolar space has widened He could not prevent all deformity if he would No justifiable force would bring the malleoli close enough to clasp as they should the articular process of the astragalus

After two or three months, during which time special efforts have been made to prevent the threatening deformity, the dressings are finally removed and the patient left to himself and a cane At this time the deformity is not great, *but the tendency to deformity is very great*, and the disability of the joint is almost total The special dressings have held the deformity in check, but all dressings removed and weight borne upon the injured ankle, and the ruin at once becomes apparent even to the patient and his friends So slight, apparently, was the deformity when the dressing were left off at the usual date in dislocations, that the inexperienced surgeon will incline to believe that rest and splints have done all they can do, and that exercise will complete the cure of the injured joint Fatal mistake! It is of the utmost importance that rest and splints should be continued In no other way and by no other means can we keep the deformity and disability within their smallest limits A steel support reaching from foot to knee, as in *talipes valgus*—a deformity our case much resembles—should be constantly worn when out of bed Under no circumstances should the injured limb be subjected to weight unless the ankle is supported by an efficient splint, and this adequate support must be kept up until the tenderness, pain, and weakness have disappeared, which will certainly not be short of a year, and it may take two years

But the inexperienced surgeon of our hypothetical case, at the end of two or three months, surrenders his patient to a cane and exercise The patient begins timidly to bear some weight on the injured ankle Even slight weight brings discomfort, but being a determined fellow, and being told that exercise will strengthen the foot, he bravely walks on the foot with the aid of his stick, but it is a limping, painful gait, growing more painful every day until the disability of the ankle is complete In alarm he sends for his surgeon to "break the leg over" The removal of the sustaining splints and the bearing of weight on the ankle result in displacing a foot that was not tied in its place by internal lateral ligaments What was only a slight displacement, but a great tendency to displacement, has by injudicious management become an ugly deformity and a painful disability

---

CLINICAL NOTES ON THE TREATMENT OF PULMONARY DISEASES BY SATURATED VAPORS AT A HIGH TEMPERATURE

Read before the Mississippi Valley Medical Association, at Crab Orchard, Ky., July 14, 1887

BY G W McCASKEY, A M, M D,

PROFESSOR OF DISEASES OF THE CHEST AND THROAT, FORT WAYNE COLLEGE OF MEDICINE, FELLOW OF THE AMERICAN ACADEMY OF MEDICINE, ETC

The use of saturated vapors at a high temperature in the treatment of pulmonary diseases was made the subject of a paper presented by the author to the Section on Practice of Medicine, etc, at the late meeting of the American Medical Association, in Chicago To that paper, which is published in THE JOURNAL of July 23, I must refer you for a full discussion of the principles upon which the treatment depends The importance of the subject of topical medication of the lungs can scarcely be overestimated The meagre successes which have heretofore crowned our efforts, instead of repressing the true spirit of scientific investigation, can only serve to spur it on to renewed attempts The accessibility of the respiratory organs, although not so easy as at first thought might appear, is yet sufficient to fully justify the therapeutic methods in question

The advantages of saturated vapors at 140° to 160° F over other forms of medication, seem to me sufficiently apparent in the light of acknowledged laws and a considerable clinical experience It is for the purpose of calling attention to this clinical experience, which was necessarily crowded out by the purely scientific discussion in the paper above referred to, that this subject is again presented It is not my intention to offer a record of cases from my note book, but rather to speak of the clinical methods and results in a more general manner A little consideration must first be given to the technique of the special form of apparatus which my experience and experimental investigations have led me to adopt

The apparatus, which I herewith present to you, is capable of holding at a complete degree of vapor saturation one cubic foot of air This quantity will more than supply the respiratory volume for one

minute, however deep the respirations may be, and the same quantity can be heated and saturated in about that length of time, so that a uniform condition can be maintained The only appliances required in addition to the vaporizer are a spray tube and a compressed air cylinder When the air in the vaporizer has been heated to the desired temperature, or while it is being heated, a dense spray is thrown in This spray, entering the heated atmosphere, is instantly vaporized, and this whether it holds in solution volatile or non volatile agents So far as I know this is the first effort at a systematic and scientific application of saturated vapor to the respiratory organs by a mechanism which is constructed with a view to meet the physical conditions present The dry and wet bulb thermometers furnish an accurate means of estimating the quantity of medicine held in solution in the vapor, even to the minute fraction of a grain, while the reduction of temperature which it undergoes in passing into the respiratory organs, in so far as that can be estimated, furnishes an accurate measure of the quantity deposited

As I have pointed out in the paper already referred to, air saturated at 158° F is more than 30 per cent vapor , and assuming that the respiratory organs would cool it down to 113° F , it would deposit 69 per cent of its contained vapor These figures are not based upon hypotheses, but are simply mathematical statements deduced from incontrovertible and fully accepted physical laws The condition of this medicine when deposited upon the mucous lining, is that of a liquid holding in solution the medicine contained in the original menstruum, and of precisely the same strength There are no problematical factors or additions, as in the case of the steam atomizer, where the steam mixes in uncertain proportions with the pulverized solution The secretion with which the mucous lining is constantly bathed is of course an obstacle to the local effects of the medicine But this objection applies to all other methods of topical medication, and with even greater force than to this If the deposit of vapor is kept up sufficiently long, the mucus must be correspondingly diluted and thinned, and the structures beneath rendered more accessible

Whatever hypothetical objections there may be, however, to the local action of agents applied to the respiratory lining, they are completely refuted by the results of clinical observations The rapid absorption of vaporized anæsthetics, along with many other facts, clearly proves that the mucus which bathes the bronchial lining is not such an impassable barrier as some would have us believe Besides all this, let us not forget that the mucous glands, and consequently the mucous secretions, are entirely absent, not only from the alveoli and air cells, but also from the bronchial tubes of small size [1] Consequently any agents carried into the small bronchial tubes finds no tenacious mucus, or any other kind of mucus to guard the structures beneath

The sensations of the patients, in so far as these can be trusted, are proof of the deep penetration of the vapors, if any proof were needed A feeling of warmth pervades the entire chest, its intensity depending upon the temperature of the vapor, together with the depth and number of consecutive respirations Occasionally considerable coughing is produced But in the large majority of patients toleration is soon established Also in some patients a sense of suffocation is produced by the vapors of higher temperature, which can not be overcome One or two patients could not respire above 130° or 135° F

The quantity of spray required for each treatment is quite large About ℥iss–ij of solution will be converted into spray and vaporized for each treatment of ten minutes' duration I use an air-pressure of about 15 lbs , and keep the spray going during about one half or two thirds of the time of the treatment, relying, of course, upon a comparison of the thermometric scales as to the completeness of saturation So long as the wet bulb thermometer stands as high as the dry, no additional spray is required, as it would simply fall to the bottom, the air being already charged to the fullest extent possible

My experience has been principally in the treatment of phthisis and bronchitis, in both of which diseases I have used pneumatic treatment in combination with the saturated vapors My opportunities for comparison extend over a period of about fourteen months, during which I have treated about sixty cases Increased intra pulmonary pressure has been used in nearly all the cases, and a comparison can only be made under similar conditions between the use of the vaporizer, and simple spray or the steam atomizer As regards sprays at ordinary temperatures, I have no hesitation in pronouncing them comparatively inefficient in lesions of the deep respiratory passages I do this from both theoretical considerations and practical observations, and with a full recognition of their value, and, indeed, their superiority in laryngeal and tracheal inflammation Aside from their failure to adequately reach even the deep bronchial structure, sprays have a very objectionable feature in the treatment of lesions located here, in their profuse deposit in the mouth and throat where they are not needed

The steam atomizer fills the indications much more completely, but lacks in the very essential elements of precision, and complete control, both as regards strength of medicine used, and temperature of application The steam atomizer, although much superior to the ordinary spray, can not be made effectually to do the work of the "vaporizer"

I have lately been using a 1 per cent solution of carbolic acid in the treatment of phthisis and the purulent stage of bronchitis Although it is not open to demonstration, and therefore must be asserted guardedly, yet I am very fully convinced that the vapor, aided by the mechanical effects of increased air pressure, does penetrate, and is deposited upon, the walls of patulous tubercular cavities The modification of secretions and of general symptoms can scarcely be explained upon any other hypothesis, besides which the physical laws and conditions are such as to fully justify this explanation

[1] Landois vol 1 p 220 Frey's Histology p 450

A variety of other agents has been used, especially $HgCl_2$, 1-1000 to 1 2000, but I think the best results have been obtained by the use of carbolic acid

In the treatment of laryngeal affections I do not think that saturated vapor offers any advantages over the common spray or steam atomizer The quantity of medicine deposited in the larynx is probably not so large as it would be with the spray or steam atomizer, but I think that theoretical considerations and practical results justify the conclusion that for the deep portions of the respiratory tract it is greatly superior to these or any other method with which I am acquainted

With the combined effect of pneumatic treatment and saturated vapors, I have seen expectoration diminish and the pathogenic organisms of phthisis grow less and disappear I do not mean to say that this has been the rule, for with this or any other treatment at present known the arrest of advanced phthisis must be the exception, and a fatal termination the rule But I think that a method of treatment which appeals so strongly to our judgment through our knowledge of physical laws, is at least entitled to careful and thoughtful consideration

In many cases of intractable bronchitis the results have been so signal as to remove all doubts, in my own mind, regarding the superiority of this method These patients have been treated almost to the exclusion of the whole list of nauseant expectorants, the principle effect of which, in my opinion, is to disturb digestion and destroy appetite There is an *a priori* absurdity in mixing a teaspoonful of an expectorant mixture with some fifteen or twenty pounds of blood, as is done after absorption, and then expect a tangible result upon an extensive inflammatory process involving almost the entire bronchial lining The dose, when it reaches the lungs through the laboratory of the portal circulation, has reached so many "dilutions" that it ought to satisfy the views of Hahnemann's most ardent disciples While very far from denying internal medication a legitimate place in the therapeutics of pulmonary disease, yet I would make it as subordinate as it is acknowledged to be in the treatment of other inflammations as accessibly located as these When dealing with a cystitis or pharyngitis, or even a gastritis, we do not rely upon the introduction of medicinal agents into the circulation, from thence to reach the seat of morbid action by a circuitous route, and in infinitesimal dilution But we apply our remedial agents to the diseased focus by means of the catheter, the gargle or probang and the siphon tube or stomach pump Constitutional measures are not neglected, but they are not relied upon as the principal method of treatment

The future, nay I believe the present therapeutics of certain pulmonary diseases must rest upon this basis of local therapeutics, backed up by such constitutional measures as will improve nutritive processes in general, and consequently those of the lungs in particular

Ft Wayne, Ind

CEREBRAL SOFTENING, WITH REPORT OF A CASE

BY C N BLOUNT, M D,
OF HAGERSTOWN, IND

Daniel N, aged 52, carpenter, twenty five years before his last sickness was suddenly attacked with a severe convulsion There were no premonitory symptoms, excepting that for a little while before he stammered in attempting to talk He had about twenty convulsions in all The paroxysms were very severe, occurring sometimes once or twice a day, and then a day or two would intervene before their return, and thus continuing until they entirely ceased in a short time There was no tendency to a return of the convulsions until his last sickness There was no paralysis except aphasia for a short time He was an invalid, however, for about a year, when he was sufficiently restored to resume his trade, which he continued during the intervening years till his last sickness He did not seem in any way different from his former self excepting a loss of memory His wife thinks that his memory was more defective in every way than before the attack, but especially in remembering where he had placed anything he had been using

There was a small tumor on the back of his head, which gradually grew during these years to a diameter of three inches He occasionally complained of severe pain in it It was there long before the above mentioned attack

In April, 1885, the tumor was removed by the knife After the operation he continued at work until October, when he was compelled to give up His wife thinks, however, that he was never well after the operation He was peevish, fault finding and very irritable, becoming very angry at little things He now frequently complained of headache, which daily increased He would sometimes say that the old pain was in the back of his head, and would think that the tumor was returning For a month or more before he took to his bed, he was very much indisposed He acted strangely, slept badly, was feverish at night, complained of numbness of limbs, was costive There was no nausea, and his appetite was good all the time He persisted in being at work up to October, 1885, when he had to take his bed

He occasionally had slight convulsions during October, November and December Sometimes during the summer he would forget words, but this was now much more noticeable Most of the time during his sickness he had hemiopia, a few times he had diplopia He spoke of this last trouble only on two or three occasions, but the hemiopia was rather persistent There was a gradual failure of both physical and mental forces until he was a complete physical wreck and demented, taking no interest in anything During the latter part of his sickness there was partial paralysis of the right side, more marked in leg than arm There was also paralysis of the tongue and muscles of the pharynx This was very distressing during the last two months of sickness He could scarcely speak or swallow He became very much emaciated, and died in April, 1885, about one year after the removal of the tumor

Dr Buntin and I made an autopsy in the presence of Drs Moore and H C Boyd On removing the calvaria the brain appeared a little flattened, the cortical vessels were much enlarged, giving the surface a pinkish color Having loosened the brain and lifted it from its bed, on inspection it did not seem to be extensively diseased The cortical portion of the posterior lobe seemed thinner and much paler than that of the other lobes On separating the hemispheres we found the entire covering a thin shell not more than one fourth inch in thickness The brain tissue of each hemisphere was softened to about the consistency of custard, and was of a grayish white appearance There was not any healthy brain tissue in either of the hemispheres, but the entire cerebral substance was softened and broken down The cerebellum was healthy, save that at a few points it seemed to be softening

Edes, in Pepper's "System," says "A general softening of the whole brain does not and cannot occur, since a vascular lesion sufficient to cause anæmic necrosis of the whole brain must cause death before softening would have time to take place" Here was a case in which the blood supply was cut off from both cerebral hemispheres and softening did take place throughout the entire cerebral portion of the brain, and the man lived seven or eight months, or perhaps twenty six years, while this process was going on We did not in this investigation examine the vessels as we should have done, but we know that they were completely plugged, for there was not a remnant of a vessel in all this soft mass of matter If Edes included in his statement the cerebellum, of course he must be correct, but if he means the cerebrum alone he is mistaken, as demonstrated by this case The left side of the brain is the one usually softened, because the vessels of that side are more readily entered by an embolus The middle and anterior cerebral vessels are branches from the internal carotid, the posterior cerebral from the vertebrals They are united by communicating vessels at the base of the brain, forming the circle of Willis They make such a perfect anastomosis that if either trunk were obstructed by an embolus, thrombus, or any other cause, before the communicating branch is given off, the brain would still be nourished by means of this very wise anatomical arrangement If, however, the obstruction should occur beyond the communicating branches in either vessel, that part of the brain receiving its nourishment therefrom must become anæmic and die, because these vessels do not anastomose as vessels in other parts of the body, and hence a collateral circulation cannot be established to nourish the portion of the brain thus deprived of its blood supply If paralysis exists it is usually on the right side—the left brain being more frequently softened The topography of the brain is so well understood that an expert can almost always locate the part of the brain deprived of its blood supply—but he cannot so readily differentiate the particular form of the trouble or character of the lesion producing the symptoms in a given case My observation of such cases has been too limited for my opinion to be of much value I saw the case reported about three months before death Having the history given as above detailed, and reasoning from it, I was inclined to think that there was a tumor that had existed for a long time, and that it had produced the former symptoms, and that from some cause, it had not been growing until, on the removal of the external tumor, it took on new action and produced all the symptoms present If that was not the condition, then I thought that beyond doubt there was much softening—which was found

Da Costa says that there are no pathognomonic symptoms the presence of which would enable us to declare, without hesitation, that we are dealing with a case of softening of the brain, or the absence of which would justify us in concluding that it does not exist Nothnagel says the diagnosis of hæmorrhage, embolism or thrombus cannot, in any given case, be unreservedly made

MEDICAL PROGRESS.

Treatment of Burns and Scalds —Professor Mosetig, during the last five years, has treated with iodoform forty eight severe cases of burns and scalds with the most satisfactory results The danger of iodoform intoxication in burns, he believes, is merely theoretical, as neither he nor others who treated burns with iodoform had, when using certain precautions, ever met with bad concomitant effects The action of iodoform is twofold—it is both analgesic and antiseptic The patients, according to Dr Mundy's experience, which Prof Mosetig fully confirms, obtain ease a few minutes after the application of iodoform to their burns, and are soon fit to be moved The patients, in Prof Mosetig's wards, repose quietly and without pain in their beds, they recover more rapidly, with only moderate and consequently less exhausting discharges, and with smoother cicatrices, than those differently treated, and if there is no possibility of saving the life, euthanasia at least is procured Iodoform, although inert against the dangers to life from oligocythæmia and the nervous shock, guards against the danger of sepsis

Prof Mosetig, differing from the majority of surgeons, uses iodoform in very limited quantities only He either does not employ the powder at all, or when so in rare instances, he sprinkles it by means of an insufflator in very thin layers, only on those places where the integument has been burnt in its whole thickness, and has assumed a parchment like appearance As a rule he covers the injured parts directly with compresses of iodoform gauze, not prepared in the usual way, by thickly dusting the gauze with the powder, but by impregnating with an etheric solution of iodoform the purified gauze, which has previously been freed of grease He proceeds in the following manner After opening and excising the vesicles, and cleaning the burns with cotton-wool, which had been steeped in a ½ per cent solution of table salt, and well pressed out, he covers the wounds with dry compresses consisting of several layers of iodoform gauze, prepared as stated above, of corresponding

size, which are exactly and smoothly laid over the whole surface of the injury Over this an equally large or somewhat smaller piece of gutta percha tissue is placed, taking care that it does not form folds or creases The whole is wrapped in a very thick layer of medicated absorbent cotton wool which overlaps to a great extent the compresses, or, better, surrounds the whole limb or injured part of the body This cotton wool is finally fixed by several turns of bandages, which at the same time exert a gentle pressure This simple dressing, which, moreover, has the advantage of taking up very little time, is allowed to remain, without being changed, as long as possible, *i e*, as long as cleanliness permits, and no rising of the temperature takes place

The secretions from the wound drain off beneath the gutta percha tissue, and are taken up by the absorbent cotton wool Slight staining of the bandage is no sufficient indication for renewing the dressing, which ought to be permanent, in case of real imbibition and offensive smell, only the external dressing has to be removed and changed, the iodoform gauze, and the gutta percha covering, however, should not be interfered with

In case, in the meanwhile, fever should set in, which betrays by its character septic causes, generally the demarcation and separation of the mortified part having commenced, or a retention of the secretion of the wound having taken place, the dressing must be removed, the abscess opened, and free discharge of the pus secured the mortified shreds and the eschars must be removed by means of forceps and scissors The new dressing is put on in the same manner as the first one

The impermeable covering of gutta percha tissue is very essential, and ought never to be omitted, because the drying on and sticking to the wounds of the gauze, stiffened by the imbibed secretions, is always injurious, and may moreover cause, like a scab, retention of the secretion The discharge may be allowed to dry in the external portion of the dressing, but never on the wound itself

By the permanent iodoform dressing, the infection, both by the air and by contact, is prevented, and burns of the second degree, as a rule, heal under a single dressing, in burns of the third degree, aseptic separation of the eschar, with but slight secretion, frequently takes place, and even if the latter be not the case, the granulating surfaces heal in a far shorter time, and the cicatrization is smoother, more even, and altogether less disfiguring than in non aseptic treatment

In burns and scalds of the face the mode of dressing described will, of course, be impossible, instead of it an iodoform vaseline ointment (1 20) is employed, and covered with a mask of gutta percha tissue The ointment has to be daily renewed, and is always spread on to the thickness of a knife blade —*London Medical Record*, July 15, 1887

SYMPATHETIC AFFECTIONS OF THE EARS —DR F W BENNETT says

Two cases which have occurred recently in my practice seem to present examples of a sympathetic relation between the ears The first was a man, aged about 25, who had suffered from deafness for several months The hearing distance on either side was about six inches On examination mucus was diagnosed as being present in the middle ear on both sides I incised the membrane on the left side, and by syringing through a Eustachian catheter removed a considerable quantity of mucus The hearing distance increased so more than two feet To my surprise, there was a corresponding improvement on the other side, this latter was, however, only temporary, and had disappeared three days later The left ear continued much better, but no further improvement occurred on the right side until I removed mucus by incision

The second case is more interesting A painter, somewhat anæmic, complained of recent deafness and pain on the left side, with constant humming on the right On examination, I found a recent collection of cerumen on the left side, but nothing abnormal on the right I syringed away a soft ceruminous plug from the left ear, when the patient said that not only had the deafness and pain gone, but the humming on the right side had ceased

Possibly in the first case excitement, due to the unpleasant operation, so stimulated the auditory nerve as to render its perceptive power temporarily greater In the second case, however, there was no excitement, no prolonged syringing was required, and nothing whatever was done to the right ear I could not but conclude that the soft plug had sufficed, in the patient's anæmic condition, to set up irritation, causing pain on the same side and tinnitus on the opposite —*The Lancet*, July 30, 1887

INTRAVENOUS INJECTIONS OF ARTIFICIAL SERUM IN CASES OF ACUTE ANÆMIA —The *Paris Medical* publishes an interesting communication of DR PREGADINO concerning subcutaneous injections of artificial serum The author experimented on a large number of dogs, which after considerable and rapid loss of blood, revived after having had artificial serum injected into their veins The saline injection, or artificial serum, is composed of 6 grammes of pure sea salt dissolved in 1 litre of boiled water, and then filtered Before injecting, care must be taken to render the skin as aseptic as possible by washing with antiseptics The injection should be made at a point where there is plenty of cellular tissue, from 20 to 30 cubic centimetres of liquid per dose In all, the quantity injected must be about one half of the quantity of blood lost A slight massage aids the diffusion of the liquid The syringe must be aseptic The sensibility being deadened by loss of blood, there is not very much pain The immediate results of the injections are renewed sensibility, cessation of contractions, and of cardiac pressure, followed by progressive return of vital manifestations The process is simple, free from danger, and sufficiently rapid for acute cases The author recommends its trial on the human subject —*London Medical Record*, July 15, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

RELATION OF ERYSIPELAS TO PUERPERAL SEPSIS

DR A MACLAREN, of St Paul, in a paper appearing in another column, reports a number of cases of puerperal sepsis, alleged to be caused by erysipelas His argument is, briefly A woman is attended during a normal confinement by a medical man, who had been exposed recently to erysipelas or was himself the subject of the disease The woman has puerperal fever There is no epidemic of puerperal fever, at that time in St Paul, possibly, not even another case Ergo, erysipelas is the probable cause of the puerperal fever It seems scarcely necessary to point out the fallacy in this mode of reasoning Dr MacLaren premises his paper by a statement of the Semmelweis[1] theory of puerperal fever,—that "Every case arises from the absorption of decomposing organic matter from lesions of the genital tract" He accepts this theory

The possible sources of infection are well nigh innumerable Puerperal sepsis, itself, is only one cause, and its exclusion, when it is possible, does not, of course, eliminate all other sources of infection except erysipelas The responsibility for infection attaches primarily to the physician and nurse The nature of the antiseptic precautions—whether adequate or not—upon the part of these attendants, is not stated specifically by Dr MacLaren No logical conclusion with reference to the relation between erysipelas and the cases of puerperal sepsis, reported in the article under discussion, can be drawn So far as Dr MacLaren's argument is concerned, erysipelas may have caused the puerperal fever, or it may have sustained no causal relation whatever The experience of the practitioner, mentioned in the paper,—"Every woman that I saw during that last three weeks had a chill on the third day whether I touched her or not,"—reminds one forcibly of Rutter's sad history, and the fetichism of the pious and venerable Meigs The latter accomplished obstetrician once remarked that Dr Rutter was "merely unhappy in meeting with such accidents through God's providence" He also propounded the question, "Did he distil a subtle essence which he carried with him?"

The causal nexus between erysipelas and puerperal sepsis is a traditional belief especially among English and American observers The best textbook on the diseases of the puerperal period, in the English language, with which we are familiar, contains the following statement "Many physicians still doubt or deny that diphtheritis or erysipelas can cause puerperal fever because they have seen diphtheritis and erysipelas in normal childbed In diphtheritis we have a putrid wound in the throat, and in erysipelas a phlegmonous inflammation The secretions of either affection may produce septic infection when brought in contact with fresh wounds of the same patient, and do not infect the system at the place of origin when the avenues to infection are closed" The view, thus clearly expressed, is doubtless the safest as regards practice, in the present state of knowledge The statement, however, that the causal relation between erysipelas and sepsis, in general,—puerperal sepis, in particular,—has been demonstrated, is not true

Regard, for a moment, a little of the recent literature of this subject Volkmann[3] has emphasized the importance of clearly distinguishing erysipelas, as a disease *sui generis*, from the phlegmonous processes Matthews Duncan[4] has shown by the London mortality records, 1848–1874, that puerperal fever is not an epidemic disease, in the true sense of that term, and that there is no coincidence in point of time between the prevalence of erysipelas and that of child bed fever Hugenberger[5] has pointed out the fact that erysipelas is a very infrequent complication of the puerperium Out of 7536 puerperal women, in the Lying in Hospital of Moscow,—1876–1877—erysipelas was observed once in every 500 cases, and

[1] Aetiologie des Puerperalfiebers 1861 pp 52 103 Semmelweis demonstrated that child bed fever was caused by (1) cadaveric poison (2) discharge from carcinomata (3) pus from a penetrating wound of the knee joint From these facts he arrived at his universal proposition by a process of induction

Joseph Kucher Puerperal Convalescence and the Diseases of the Puerperal Period 1886 p 208

[3] Pitha Billroth s Chirurgie —Erysipelas

[4] On the alleged occasional prevalence of puerperal pyæmia and of erysipelas Edinburgh Med Journal 1876

[5] Archiv f Gynaek Bd xiii p 409

once in every 120 cases with fever He has demonstrated its sporadic occurrence

The discovery of the streptococcus of erysipelas, at a comparatively recent date, by Fehleisen, constitutes by far the most important event in the history of the development of the subject Gusserow[6] holds that erysipelas and puerperal sepsis have nothing in common He cites two cases of erysipelas, occurring during the latter half of pregnancy, as a purely accidental complication The puerperium, in the first case was normal The patient, in the second case, died a few moments after delivery The autopsy (v Recklinghausen) demonstrated that there was no trace of puerperal sepsis—the uterus and adnexa, pelvic peritoneum and connective tissues being normal Lomer[7] refers to a case of *erysipelas faciei*, occurring in a woman, nearly at term Labor was probably precipitated by the elevation of temperature The body of the patient was not touched by any of the attendants, and the patient herself was obliged to cleanse the genital tract The conditions were as favorable as possible for the production of puerperal sepsis by erysipelas The puerperium was normal

Gusserow narrates the history of a case of *erysipelas faciei*, occurring on the fourth day of the puerperium The patient recovered, without a sign of puerperal sepsis A second case was that of a woman, attacked on the eighth day of the puerperium with erysipelas, proceeding from a fissured nipple, who died seven days later The autopsy revealed absolutely no trace of puerperal sepsis All of these cases were evidently accidental complications of pregnancy and the puerperium, and they did not cause puerperal sepsis This fact, however, does not demonstrate that erysipelas cannot cause puerperal sepsis As remarked by Dr MacLaren, "The clinical fact that a puerperal woman may have a localized erysipelas of the skin in some part of the body, and not have puerperal fever, is no proof that erysipelas cannot cause puerperal fever" In the paper mentioned, Gusserow cites nine cases of erysipelas, occurring in women who were already the subjects of puerperal sepsis The clinical histories of these cases resemble in a general way those of the cases reported by Hugenberger In these cases, of course, it is not possible to assume any causal relation between erysipelas and puerperal sepsis Neither is it possible to conclude from these data that erysipelas cannot cause puerperal sepsis, or that erysipelas may not be a sequela of puerperal sepsis

[6] Archiv f Gynaek Bd xxv, Hft 2, p 169
[7] Zeitschr f Geburts u Gynaek Bd x Hft 2, p 384

Gusserow has sought to demonstrate experimentally that erysipelas has nothing in common with puerperal sepsis He inoculated six rabbits with pure cultures of the streptococcus of Fehleisen, in two animals, a small quantity of the fungus was placed free in the peritoneal cavity, in two, in contact with the wounded peritoneum, in two, in the subserous connective tissue Negative results were observed—absolutely no trace of sepsis upon post-mortem examination, some time after inoculation Control experiments—the injection of the micrococci into the skin of the ear, two rabbits—resulted in the typical development of erysipelas Winckel[8] concludes from the observation of 42 cases of puerperal erysipelas that "puerperal erysipelas occurs in a definite relation to, and in intimate union with, puerperal sepsis, and that the former, as the latter, is a genuine wound infectious disease, arising through local infection with the chain forming micrococcus, which can be inoculated alone or in connection with other micrococci"

Evidence, collected from clinical observation, pathological investigation, and experimental research, is totally inadequate, at the present time, to demonstrate the nature of the relation between erysipelas and sepsis in general—puerperal sepsis in particular In the midst of this confusion of ideas, and in this conflict of opinion, it is wisest to assume that the nature of the relation is necessary and causal Fortunately, however, the question exercises slight influence upon practice, since the adequate disinfection, instituted against known sources of infection, involves protection against erysipelas

NEW YORK BUREAU OF INFORMATION AND THE MEDICAL CONGRESS

To afford all possible aid to those coming from foreign countries to attend the International Medical Congress to assemble in Washington Sept 5, a Bureau of Information has been formed in New York, composed of twelve or fifteen leading physicians, among whom are Dr Wm M Smith, Health Officer, Dr Joseph O'Dwyer, Dr J Lewis Smith, of New York, and Dr Wm H Pancoast, of Philadelphia The following circular in English, French and German has been sent to the European medical journals and is to be placed on all the incoming steamers until the time for the Congress to be in session The circular is as follows

"The 9th International Medical Congress will convene in Washington, on Monday, September 5th

[8] Ueber das puerperale Erysipel, Munchen, 1885 Jos Ant Finsterlin, p 25

Washington is 200 miles from New York, six hours by railroad

"Foreign Steamers to New York land at New York or at Jersey City or Hoboken, opposite New York The New York Bureau of Information have engaged a reception parlor in the Hoffman house, corner of Broadway and 25th Street The Broadway car line, which is crossed by the car lines from the steamer landings, passes in front of the hotel

"Rooms at the Hoffman House, which is conducted on the European plan, can be obtained through the committee at a reduction of 25 per cent One or more of the Reception Committee will be in attendance between 2 P M and 4 P M each day, on and after August 20th At other hours the Clerk of the Hotel will act for the Committee Members intending to attend the Congress are requested to send their names in advance to the Reception Committee, Hoffman House, New York, so that the Committee can secure for them reduced hotel and railroad rates "

AMERICAN MEDICAL ASSOCIATION —We are informed by the Chairman of the Special Committee having the matter in charge, that on account of impaired health and professional duties Dr R Beverly Cole, of California, has been constrained to decline the appointment to give the Address on General Medicine at the next Annual Meeting of the Association to be held in Cincinnati, May 1888, and the committee have secured a promise that the address will be delivered by Prof Roberts Bartholow, of Philadelphia This selection will give very general satisfaction, as it secures the services of one of the ablest exponents of Practical Medicine in our country

RATES TO THE CONGRESS —*Caution* —Let all our readers who are interested in the railroad charges for those intending to attend the International Medical Congress to convene in Washington September 5, 1887, examine carefully the official statements over the signature of the Chairman of the Transportation Committee, J W H Lovejoy, M D , No 900 Twelfth St , Washington, D C , to be found in THE JOURNAL of July 23, p 126, and of August 13, pp 223–4, that they make no mistake by not complying with the terms for securing return tickets at one third the ordinary rates

ENTERTAINMENTS CONNECTED WITH THE NINTH INTERNATIONAL MEDICAL CONGRESS —We are authorized to state that the more important entertainments, receptions, and excursions positively provided for and adopted in the Programme are as follows Monday evening, Conversazione at U S Pension Hall, from 8 to 11 P M , Tuesday evening, Visit to the Corcoran Art Gallery, Wednesday evening, Receptions by the Citizens of Washington, from 8 to 12 P M , Thursday evening, General Reception and Buffet Banquet at U S Pension Hall, from 8 to 11 P M , Saturday afternoon, Visit to Mt Vernon, and, finally, a magnificent Excursion to the Falls of Niagara, for the foreign members of the Congress and their ladies The exact time of starting from Washington and other details of this excursion will be given in due time

SUDDEN DEATH OF DR WM A BYRD —Dr William A Byrd, of Quincy, Ill , died on August 14, 1887, at Slater, Mo , to which place he had gone for a visit to his father He is reported to have been attacked with sunstroke on the 13th, and survived only about eighteen hours He was 44 years of age, and one of the most active and well known surgeons in that section of the State

VACANCY IN THE ILLINOIS STATE BOARD OF HEALTH FILLED —Governor Oglesby has appointed Dr H V Ferrell, of Williamson county, a member of the State Board of Health, to fill the vacancy occasioned by the resignation of Dr Geo N Kreider, of Springfield

SOCIETY PROCEEDINGS

AMERICAN OPHTHALMOLOGICAL SOCIETY

Twenty third Annual Meeting, held in New London, Conn , July 20 and 21, 1887

(*Concluded from page 217*)

DR CHARLES A OLIVER, of Philadelphia, read a paper on

THE EYE OF THE ADULT IMBECILE

The following conclusions were offered

1 The eye of the male adult imbecile is an organ which is capable of proper functional activity

2 By reason of early mental incapacity, the ordinary appearances seen in the used eyes of the mentally healthy are lessened in due proportion to the amount of work given to the organ

3 The eye of the imbecile, being practically an unused organ for close and careful near work, the distension of the globe and the elongation in its visual axis with consequent increase in index of refraction is almost intirely avoided, this being in direct ratio to use

4 The want of these physical changes may be

considered as significant of a type of unused, healthy adult human eyes

5 The healthy eye of the imbecile serves to teach us that the various conditions seen in the used eye of the mentally healthy must be considered as pathological changes, the representatives not only of general want of tone but of constant and frequent abuse of a delicate organ

DR S D RISLEY, of Philadelphia, reported

ADDITIONAL CASES OF HYPERMETROPIC REFRACTION PASSING INTO MYOPIA

Thirteen carefully studied cases in which the eyes with hypermetropic refraction had been observed to pass into myopia had been recorded in the annals of the Society To day the author brought forward nine additional cases, making a total of twenty two In all these cases, the state of the refraction had been repeatedly demonstrated under complete paralysis of the accomodation In every case there was well-marked retino-choroidal irritation with asthenopia Insufficiency of the internal rectus was noted in three cases, in all of which tenotomy of external rectus was performed In no case was emmetropic refraction observed at any stage of the progress The condition seemed to pass from the shallow hypermetropic ball to the lengthened myopic eye by the turn-stile of astigmation The most important measure in the treatment of these cases was considered to be the use of correcting glasses When we consider the large number of cases which at the first present the same conditions as the cases reported and who have subsequently had no return of the trouble, we cannot but think that the group of cases now presented are only those in which the treatment has failed, and that without their correcting glasses a much larger number would have pursued the same history A study of these cases has demonstrated to the author the importance of astigmatism when present in very low degree, as a factor in setting up those changes in the nutrition of the eyeball, which result in impaired resistance to even normal intraocular tension

DR SAMUEL THEOBALD read a paper on

THE PATHOGENESIS OF PTERYGIUM

The generally accepted theory of Arlt that pterygium has its origin in a marginal corneal ulcer to which a tag of conjunctiva has become attached, he thought was untenable, because if this were its usual mode of origin, pterygium would be found approaching the cornea from every possible direction, since marginal corneal ulcers are not apparently more frequent in one position than in another It is known, however, that such is not the case, but that pterygium is almost always situated directly over the recti muscles and that in a very large proportion of cases it is over the rectus internus The more recently proposed theory of Poncet that pterygium is due to the presence of microbes which tunnel their way under the corneal epitherium is open to the same objection, for this also assumes the existence of a precedent corneal ulcer The view long held that conditions which tend to induce chronic hyperæmia of the conjunctiva favor the formation of pterygium, he thought was well established Assuming that this view is correct are there reasons why localized hyperæmia of the conjunctiva should be of frequent occurrence where pterygium usually forms to the nasal side of the cornea? This was answered affirmatively The close connection between the vessels of the recti muscles and those of the anterior portion of the conjunctiva was referred to, and it was pointed out that the determination of blood to these muscles might influence the blood supply of the overlying conjunctiva, and that this would be the case especially with the recti interni since they were the largest of the straight muscles, and in close relationship with conjunctiva because attached to the sclerotic nearer to the cornea border than any of the others Abnormality in the distribution of the blood supply of the internal recti muscles and of the overlying conjunctiva, and more frequently still, disturbance in the normal relationship between convergence and accomodation, such as insufficiency of the internal recti muscles, the different varieties of ametropia These were regarded as the usual causes of pterygium through the localized hyperæmia of the conjunctiva to which they give rise

DR THEOBALD also read a paper on

RECURRENT RETINAL HÆMORRHAGES FOLLOWED BY THE OUTGROWTH OF NUMEROUS SMALL BLOOD VESSELS FROM THE OPTIC DISC

The case reported was that of a lady, 52 years of age, in whom menstruation had recently ceased During a period of nine months she had suffered with recurrent hæmorrhages into the retina and the posterior part of the vitreous humor of one eye The macula escaped serious involvement, and central vision was but little affected The hæmorrhages were supposed to be due to thrombosis of one of the larger retinal veins Finally, a nebulous outgrowth from the optic disc, extending forward into the vitreous humor for some distance made its appearance This consisted of numerous small and nearly parallel blood vessels running from behind forwards and held together by semi opaque tissue, the outline of which could be easily distinguished from the surrounding vitreous When last seen this growth had diminished somewhat in size The prognosis was regarded as regarded as favorable, the development of new vessels being looked upon as an effort of nature to repair the damage caused by the repeated hæmorrhages

DR O F WADSWORTH, of Boston I have seen several cases of recurrent hæmorrhage partly retinal but largely into the vitreous In only one could I positively say that there was a development of vessels into the vitreous The other cases have not been observed sufficiently long to show whether or not there has been a development of vessels The case referred to was that of a man seen ten years ago when he was 35 years of age When I saw him there was extensive hæmorrhage into the vitreous of one eye rendering the fundus invisible This cleared up to a certain extent leaving portions of the retina clear Then certain changes in vessels toward the periphery could be seen The other eye showed a perfectly healthy fundus except in certain places

toward the equator, where there were several patches of peri vasculitis The hæmorrhages continued to occur in the affected eye After a time there could be detected in the vitreous a nearly transparent membrane containing vessels, some of which could be traced back to the retinal vessels Two or three years later, I again saw the patient He had then been free from recurrences for a year or two There were still some vessels in the vitreous, but not so many as previously

Dr H Knapp I wish to say a word with reference to treatment The main point is not to fatigue the eyes, and to put them at rest early in the evening A waitress in a New York family suffered from hæmorrhages every time the family gave an evening party She was sent to the country and the hæmorrhages cleared up She returned and served at an evening party and again the eye filled with blood She has now given up service and for two or three months has had no trouble The treatment consists in rest, and in avoidance of everything that would produce a dropsical condition of the blood

Dr G C Harlan, of Philadelphia, reported a case of:

EMBOLUS OF THE CENTRAL RETINAL ARTERY

The patient was a clerk, 52 years of age, in good general health While reading in perfect comfort, a shadow suddenly appeared before the left eye and on closing the other, he could just distinguish large objects about the room, and in a few minutes sight was entirely gone An ophthalmoscopic examination made the next morning, showed an extensive œdema of the retina, giving the whole fundus a grayish tinge, disc pale and its margins blurred, arteries very pale, although not much narrowed, and some of the smaller branches lost in the retinal œdema, larger veins contracted in places, particularly in and near the disc, but generally of full calibre, phenomenon of visible, slow continuous circulation of blood in bead like sections well marked in superior temporal artery and vein, macula occupied by bright red patch, oval in form with its long diameter horizontal, and several minute terminal vessels in its neighborhood enlarged and apparently isolated, two small dots of retinal hæmorrhage at outer margin of disc The œdema increased decidedly for the first few days, and then gradually subsided There was still a little remaining on the 19th day, after which the patient was not seen for three weeks, when the color of the fundus was normal The visible circulation lasted only about a day and a half, disappearing first in the artery The veins refilled at their narrowed portions, and retained nearly their full calibre, while the arteries became paler and narrower until only the two main trunks could be seen and these showed white lines along their margins from perivasculitis The spot at the macula gradually disappeared The disc regained the distinctness of its outlines but remained dead white

Dr David Coggin, of Salem, Mass, read a paper entitled *Chronic Glaucoma*

Dr George C Harlan read a paper on

DANGER TO IRON WORKERS FROM THE USE OF OLD HAMMERS

A hammer was shown from which a fragment had split off, injuring the eye of a workman The constant concussion of the hammer causes it to assume a chrystaline condition and become very brittle

Dr Myles Standish, of Boston, reported a case of

RETINITIS PIGMENTOSA TREATED ELECTRICALLY

The patient was a woman 33 years of age, and was myopic—15o D She had worn glasses since she was 17 years of age When first seen, April 14, 1886, her sight had been failing for three years and for the last three months had failed very rapidly, so that she could not go on the street alone after dark On ophthalmoscopic examination characteristic patches of retinitis pigmentosa were found in the periphery of the fundus of each eye Her vision was R E $\frac{2}{40}$, L E $\frac{2}{30}$, and the fields of vision were limited to less than 20° in the vertical and horizontal axes The only treatment has been the use of constant current, of such strength as could easily be borne This has been applied once in five days during the last fifteen months Her present vision is right $\frac{2}{30}$, left $\frac{2}{25}$, and the fields of vision have now vertical and horizontal axes of 70° She now goes on the streets after dark with safety

Dr C H Williams, of Boston, read a paper on

ASEPTIC CATARACT EXTRACTION WITH IRRIGATION

The author reported five cases of irrigation of the anterior chamber after cataract extraction with a 5 per cent solution of chloride of sodium, as recommended by Dr McKeown Instead of a syringe, a glass tube was used, bearing two glass tubes blown in the side One of these was drawn out to a fine nozzle that could be easily inserted into the anterior chamber, the other had a rubber tube and mouth piece attached so that the pressure of the stream could be controlled by the operator The flask had a capacity of 50 cc, more than enough to complete any irrigation without removing the tube from the eye The irrigating instruments and the 2 per cent solution of cocaine were sterilized in the steam sterilizer, and this was not found to injure the anæsthetic properties of the cocaine The other instruments and the dressings were sterilized by dry heat at a temperature of 150° C In order to determine the efficacy of the solution of the bimiodide of mercury used for the preliminary washing out of the conjunctival sac, some experiments with plates cultures were made at the laboratory of the Harvard Medical School, through the kindness of Dr Ernst An equal amount of the bimiodide of mercury and the iodide of potassium were dissolved in water and added to 10 per cent nutrient gelatine, to give a series of strengths up to 1 to 5000 of the bimiodide to the gelatine Ten days after exposure to the air of the laboratory for six and one half hours no growth of bacteria were found on any of the plates, although on the unprotected plates, exposed at the same time, there was abundant development of colonies of bacteria Gelatine of the strength of Pana's solution (1–20 000) was then tried, and these plates

after four day's showed an average of 1 5 and 0 8 colonies of bacteria to the square centimetre of surface in the two series of plates, while on the unprotected plates the average was 10 5 For two of the cases of extraction a suture was passed through the piece of conjunctera above, and this held the wound well in apposition All of the extractions were done without iridectomy, and a layer of iodoform was dusted on the edge of the closed lids just before applying the bandage

DR O F WADWORTH, reported a case of

CONGENITAL ZONULAR GRAYISH-WHITE OPACITY AROUND THE FOVEA

The patient was a child 11 months old She was unable to sit or stand, and could not hold anything in her hands She appeared to take little notice of anything Externally the eyes were normal With the ophthalmoscope the discs did not seem to vary from the normal appearance The macula was dark red and surrounded by a grayish white opacity The remainder of the fundus appeared to be normal There appeared to be some light perception Five months later there seemed to be no perception of light The disc was sharply defined, the central vessel small The mother had had four healthy children The fifth according to the history, had been sick in a similar way as the one under consideration In all the reported cases some weakness of the general muscles was noted

DR WADWORTH also reported a case of

SEPARATION OF THE RETINA IN BOTH EYES WITH ALBUMINARIA OF PREGNANCY,—REPLACEMENT

The patient was a married woman 7½ months pregnant About the beginning of the eighth month œdema of the eye lid appeared This was soon followed by indistinctness of vision The urine was loaded with albumin, and contained hyaline and granular casts When seen by the speaker, there was a general separation of the retina in the right eye In the left eye there was also separation of the retina but not so distinct After consultation, it was decided to induce premature labor This was done and a living child was delivered Before the completion of labor a convulsion occurred for which bleeding was resorted to The patient convalesced and vision gradually returned When last seen, the discs were clearer No separation could be made out in either eye

Dr B Alexander Randall read a paper describing a case of *Coloboma of the Optic Nerve*

Dr F Buller, of Montreal, Can , read a paper describing *a Peculiar Form of Granular Conjunctivitis associated with Ichthyosis* Two cases in which this combination was present were reported

---

AFTERNOON SESSION

Dr W S Dennett, of New York, exhibited an *Ophthalmoscope in which the Mirror was substituted by an Electric Light*

Dr Lucien Howe presented a small *Pocket Ophthalmoscope with Movable Disk* Dr Howe also exhibited several *Photographs of the Interior of the Human Eye*

DR EDWARD JACKSON, of Philadelphia, presented a set of

SMALL TEST LENSES, WITH A MODIFIED TRIAL FRAME.

The lenses are one inch in diameter and the saving in weight is from one third to three fourths of the weight of those in common use The lenses are plano convex and concave, giving advantages over the double convex and concave, by lessening spherical aberration, being easier to combine together and making it possible to neutralize more perfectly spectacle glasses the strength of which it is desired to test Several lenses had been added to the series usually placed in such sets, including stronger concave sphericals and two astigmatic lenses, which had been found very convenient in testing for astigmatism It was suggested that all intermediate lenses added to the metric series should be made to divide in half the present interval of one fourth dioptry, making the interval one eighth and preserving the simplicity of the system Making the lenses smaller allows the trial frame to be made smaller, and very much lighter, so that the new frame with the new lenses weighs less than half the old frames with lenses of equal strength The temple of the frame is attached to the lower part of the lens holder, allowing the lenses to be placed in the back groove of the holder or withdrawn therefrom through the natural depression of the temple instead of across to prominence of the brow or cheek The set and frames are made by Queen & Co , of Philadelphia

Dr S D Risley, of Philadelphia, described an *Ophthalmoscope with Cylindrical Lens*

DR SWAN M BURNETT, of Washington, described a

MODIFICATION OF THE REFRACTION OPHTHALMOSCOPE WITH AN ATTACHMENT FOR USING CYLINDRICAL GLASSES

The modifications of the ophthalmoscope which were offered by the speaker consisted *first*, in a clip behind the instrument into which the cylinders in the test cases can be inserted The inclination of the axis is read on a graduation on the back of the mirror The author had found the arrangement satisfactory in verifying the diagnosis of astigmatism made by other methods, and for examining the fundus of the astigmatic eye free from its anomalous refraction , *secondly*, the superposed disks containing lenses which singly and by combination give 47 numbers [22 plus and 25 minus lenses] with a regular interval of 0 5 D up to 10 5 plus and minus, *thirdly*, a plane circular mirror with a concave tilting mirror swung in front of it The plane mirror does not interfere with the tilting mirror when in use, and when it is desired to use the plane mirror alone the tilting mirror can be detached from its upper bearing and swung downwards out of way on its lowest bearing The instrument is very light It is made by Queen & Co , Philadelphia, and its cost is about $20

DR JOHN GREEN, of St Louis, reported a case of

MYOPIA FOLLOWING IRITIS

In 1867, the speaker had been the subject of iritis

involving both eyes During convalescence, he noticed that the dimness of vision was not wholly due to lack of transparency of the media, and that vision was improved by the use of concave glasses He had occasionally observed in other patients with iritis that as they recovered vision was benefited by the use of concave glasses Last April the speaker had iritis affecting the left eye He was then able to compare the one eye with the other, and found that the myopia induced by the iritis amounted to 1 50 D This gradually diminished until it disappeared at the end of four weeks leaving the normal refraction He had been unable to find accounts of myopia as a transient symptom during convalescence from iritis

EXECUTIVE SESSION

The report of the Committe on a *Congress of American Physicians and Surgeons* was received, and the following resolution adopted

Resolved, That the American Ophthomological Society appoint a representative, and alternate, to the proposed Executive Committee of Arrangements for the Congress of special Societies, with the proviso that in making the appointment this Society does not commit itself to an approval of the present sketch in all its details

Dr Wm F Norris, of Philadelphia, was elected Representative to the Executive Committee of the Congress, and Dr D B St John Roosa, of New York, was elected alternate

OFFICERS FOR ENSUING YEAR

President—Dr William F Norris, of Philadelphia.
Vice-President—Dr Hasket Derby, of Boston
Secretary and Treasurer—Dr O F Wadsworth, of Boston
Corresponding Secretary—Dr J S Prout, of Brooklyn

The following were elected to membership
Dr George Cutter, of Brooklyn, Dr D C Cocks, of New York, Dr H S Oppenheimer, of New York, Dr Charles McIlvaine, of Trenton, and Dr Daniel De Beck, of Cincinnati

The next meeting of the Association will be held at New London, Conn , on the third Wednesday of July, 1888

FOREIGN CORRESPONDENCE

PRAGUE [1]

Gussenbauer, his Methods—Enlargement of Cervical Glands—Tuberculosis of the Cheek—Fistulæ from Osteo-Myelitis of Femur—Litholapaxy—Genu Valgum—Resection of Intestine for Gangrene—Chiari his Work and Laborotory—Unique Skull

Dear Dr Fenger —I arrived in Prague April 26, and at once sought Prof Gussenbauer, who impressed me very favorably He is about 44 years of age, and blessed with a vigorous, healthy constitution His aspect and behavior indicate that he is a hard worker He has charge of the surgical wards in the Stadtkrankenhaus, which contains 120 beds and affords a rich material for clinical teaching Hardly a day passes but he performs two or more capital operations He is a good lecturer and a splendid teacher In his Klinik, when a case is shown, one of the assistants reads a short history, which is followed by brief remarks with special reference to a correct diagnosis by Gussenbauer After all the material for the day has been presented the operations begin The antiseptic solution for irrigation is a 1 1,000 solution of corrosive sublimate, and a 4 per cent solution of carbolic acid for the instruments As a dressing for wounds a small compress of sublimated gauze is used, over which a copious dressing of dry aseptic hygroscopic gauze is applied, and the whole is covered with a cheap impermeable rubber cloth I can only give you a very brief account of what I saw during my three days with Gussenbauer

The first case was one of enlargement of the cervical glands on one side in a woman 40 years of age The history showed that when she was a girl a few of the submaxillaries became swollen, and remained in this condition stationary for twenty years Two years ago the same glands increased in size, and additional glands in the direction of the lymph current became involved It was assumed that the primary enlargement was a simple hyperplasia, and that the recent progress was due to tubercular infection, in other words, the hyperplastic glands had furnished the soil for localization of the tubercle bacillus The removal of the glands made a deep and very careful dissection necessary, as some of them were in close contact with the large vessels of the neck The internal jugular vein was laid bare for three inches Wherever it was deemed necessary the division of parts was made between compression forceps

The second case was one of tuberculosis of the cheek in a man 50 years of age The swelling had ulcerated externally, and where the skin had given way the surface was covered with flabby granulations The mucous membrane of the mouth was closely attached to the swelling The whole mass was rapidly excised, hæmorrhage carefully arrested and mucous membrane sutured, while the external large defect was covered with a flap taken from behind the ear

The third case was that of a boy who had suffered from an acute attack of osteo myelitis of the lower end of the femur several years ago, and who now had numerous fistulous openings leading to the primary location of the disease Numerous incisions were made down to the bone, but no central reservoir could be located, and the whole lower end of the femur appeared to be covered with fungous granulations which contained a number of small spiculæ of bone The granulations were carefully removed with a sharp spoon, and the different cavities were drained and some of them packed with iodoform gauze

The fourth case was one of litholapaxy in an old man who had been relieved and apparently cured by the same operator on two previous occasions On measurement it was found that the stone measured 3 cm Chloroform was administered, and the instrument for crushing was introduced four times, and each time a number of seizures were made and the evacuator removed a large mass of detritus After

[1] By permission of Drs Fenger and Senn

the last crushing and evacuation the interior of the bladder was carefully explored, and no fragments could be detected Towards the last a small lithotrite was used for seizing and crushing of small fragments The whole operation lasted nearly an hour

The fifth case was a genu valgum I had seen so many cases of osteotomy for this deformity that I was very anxious to witness a bloodless procedure for the correction of the false position Professor Gussenbauer has for a long time abandoned the cutting operation, and substituted for it the simple *redressement* He showed me several dozen of photographs taken before and after treatment, and the final results certainly compare favorably with those obtained by osteotomy The advantages of this treatment consist in an absolute safety against infection, and in requiring less time on part of the patient After the patient is fully anesthetized he is placed on his side, and the surgeon puts the limb upon his right shoulder in such a position that the convexity at the knee is directed upwards With both of his hands he makes forcible interrupted pressure over the knee, and if his force is not adequate to correct the deformity one or more assistants help to increase the force The straightening is gradually accomplished, and often attended by an audible noise caused by the rupture of ligamentous structures The whole object of the operation must be accomplished at one sitting, and the proper axis of the limb must be completely restored In the case I saw the deformity was considerable, and the patient otherwise a healthy young man It required the combined efforts of the operator and his assistants to properly straighten the limb After the operation the limb is at once secured in a plaster-of Paris splint After three weeks an interrupted plaster splint is applied, with hinge joints on each side, and the patient is allowed to walk without the aid of crutches, Gussenbauer has never observed any unfavorable results after this procedure, and in ordinary cases confidently expects a favorable result The patients are required to wear a lateral support for at least six months in order to prevent a recurrence of the deformity I am satisfied that, in the milder forms of genu valgum and varum, this treatment is more applicable than osteotomy, and should always be tried before resorting to the more serious measure of causing a fracture

Prof Gussenbauer is justly proud of a case which he has now in the hospital in which resection of the intestine for gangrene resulting from strangulation was successfully performed The abdominal wound is healed, the bowels move regularly and the patient can be considered entirely out of danger Such a result must be a great satisfaction to the surgeon, and encourage him in the future to resort to desperate measures in desperate cases

I had the pleasure of meeting the distinguished professor of pathology, H Chiari, at the house of Professor Gussenbauer, where we spent several interesting hours around the dinner table The next morning I witnessed an autopsy at the Children's Hospital and had an opportunity to see and hear how accurately the work is done Prof Chiari also showed me through the splendid laboratory and demonstrated many interesting specimens in the museum Although a comparatively young man, Chiari stands in the front rank of German pathologists and the profession may confidently expect that through his energy and enthusiasm many new discoveries will be made I also examined the splendid anatomical collection under the guidance of Dr Rex, prosector of anatomy This collection contains a unique skull The cranial bones throughout are at least an inch thickness, perfectly solid, and the skull is so heavy that it seems to be composed more of stone than bone N SENN

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Alvelos in Epithelioma—Physiological Effects of Massage—Duration of Life—Borax and Boracic Acid as Food Preservers and Antiseptics

Several cases of epithelioma of the face and lips are claimed to have been cured with the juice of alvelos, a plant belonging to the family of the Euphorbiaceæ It is said to act as an irritant and to destroy the diseased tissue, which was in each case quickly replaced by healthy granulations of the different kinds of alvelos, male, female and wild, the second is considered to be the most efficacious in this respect The best results are obtained with the juice in a concentrated or solid form, like an extract, and with the addition of vaseline or tanoline This preparation is applied with a brush to the affected part (previously washed with a two per cent solution of carbolic acid), which is then left exposed to the air for at least one hour It is afterwards covered with lint The treatment is repeated every two or three days, but never more than once in the course of twenty four hours, as the pain is very severe The treatment is more speedily successful when begun before ulceration has set in

Dr Eccles has recently given some interesting observations on the physiological effects of massage Four distinct manipulations were described, and their immediate effects on the human tissues and functions as observed by Dr Eccles in a series of experiments on healthy persons noted *Effleurage* stimulated the skin muscles, produced dilatation of the superficial tissues and insensible perspiration, excited the skin reflexes, and, acting through the cutaneous nerves, increased the rapidity of the circulation and heart's beat *Petrissage* forced the lymph out of the muscles, increased the velocity of the blood current through the part temporarily decreased the size of a limb, and increased its muscular power The pulse rate was reduced, especially in abdominal kneading *Massage* and *friction* produced the same local effects as petrissage and was peculiarly applicable to joints *Tapötement* excited muscular contractions The immediate and remote effects of massage as a combination of the above named manipulations were, that the texture of the skin was improved, the sense of locality was increased, the general body temperature was raised, and the free surface temperature of a part under

massage become higher than that of the rest of the body while abdominal massage decreased the surface temperature of the extremities A course of mas sage of one month's duration increased the body weight, the appetite, muscles, strength and ability to sleep and work well

Dr W Playfair is a strong advocate of massage as a form of treatment He was one of the first to intro duce massage prominently into notice in England as an agent along with over feeding, and freedom from previous surroundings in the treatment of profound cases of neurasthenia or malnutrition, whose exact character we did not as yet thoroughly understand Some of the cases which were commonly counted as incurable and were a curse to their families could, he thinks, really be cured by these means He is in different what terms are used, but underlying mere criticism of the language there is apt to be a sneer at the treatment The increase in weight in healthy men was remarkable In severe cases of illness under his treatment, he is accustomed to see an in crease of ten pounds or twelve pounds a week, and many patients ultimately double their weight He has seen this treatment wrongly used in cases of locomotor ataxy and disseminated sclerosis, owing to his mistaken diagnosis and he is anxious not to run a hobby too hard, so that he has only used mas sage in a few uterine cases with a view to replace exercise Dr Powell has published a remarkable case of a lady whom he had found, as he had thought, moribund, with the right lung riddled with cavities, a hectic temperature and profuse night sweats There was abundant expectoration, in which eminent bac teriologists could find no bacteria He declined to attempt any treatment, and it was only after urgent pressure against his own wish that he did so The results turned out to be the most remarkable he had seen, the cough stopped, the patient rapidly im proved, and in two months and a half gained six stone and her lungs were practically recovered Over feeding he considers only possible when there was massage to take away the waste Dr Playfair protests strongly against the doctrine that the art of massage is a very difficult one and takes two years to learn In his opinion, half a dozen lessons are quite enough, and any nurse who could not learn all that is wanted in that time was never likely to make herself useful at it

According to Mr Edwin Chadwick the mean du ration of life during the reign of Queen Victoria has advanced from 30 to 38 years The services of paid union officers save the country £3,000,000 an nually In France the death rate is 3 per cent higher than in England, which means the loss of 112,000 lives more than at present in England In Germany with a mortality in its army the lowest in Europe, the death rate of the civil population is 6, in Italy 8, and in Austria 11 per thousand higher than here, which means in Germany a sacri fice of 135,000 lives yearly more than in England and in the two last countries of 624,000 lives annu ally over and above the corresponding waste of life in England and Wales

The extensive use of borax and boracic acid as antiseptics, especially for the preserving of fish brought from the northern European fishing grounds to English ports, has just given rise to some special observations upon this subject, which are most interesting Boracic acid has been given to several pa tients and then the turmeric test, which will detect one part in 2000 has been used, the spectro-electric tube of the French pharmacist, Vigier, has also been used In twelve cases in which the doses varied from twenty to fifty grains daily, toxic symptoms were observed after the largest doses had been taken, there was headache, vomiting and a feeling of ma laise In one instance after the use of borax for ten days, a slight acceleration of the pulse rate was ob served accompanied by increase of temperature, loss of appetite, redness of fauces, and bronchial catarrh, finally there was a well marked papular eruption upon the thighs and joints The urine commonly gave the reaction for borax ten minutes after the dose was taken, but it was not found in two days after the drug had been used by inunction In other cases it persisted in the urine for six, eight or fourteen days after the patient took it Boracic acid was found to have a decided diuretic effect, albumin disappeared from the morning urine in some cases where albuminuria existed When the greatest diuresis was produced, the boracic acid itself disappeared Borax was also found in the perspiration, saliva and fæces several days after in gestion The observations do not tend to show the danger of the use of boracic acid and its com pounds G O M

BRITISH MEDICAL ASSOCIATION

(FROM OUR SPECIAL CORRESPONDENT)

The Meeting in Dublin

One of the most successful meetings of this great Association has just been concluded, and the whole medical world has had representatives here to taste the genuine Irish hospitality, and enjoy meeting and communing with the eminent members of the pro fession here assembled The number of members registered as being in attendance amounted to 904 The weather was most propitious, and Dublin was in holiday attire

The president, Dr Banks, delivered his address in the large Dining Hall of Trinity College, taking for his subject, *The History of Medicine in Dublin*, which he handled in a most complete and interesting man ner He spoke of the admission of women to the University as being obligatory, as the charter of the University is mandatory as written, and the Colleges of Physicians and Surgeons have thrown open their doors and afforded them every possible facility

The various sections were held in Trinity College and were well attended Many papers of great merit by noted members of the profession were read and discussed, but can not be mentioned here

The address on Medicine was delivered by W T Gairdner, M D , LL D , Edinb , Physician in Ordi nary to Her Majesty the Queen in Scotland, Pro fessor of Medicine in the University of Glasgow

His subject was, "*Has the Art of Medicine Advanced during the Present Century?*" In an able manner he reviewed the progress and history of medicine from the time of Hippocrates up to the present As a proof of the greater stability of medical science in our day Dr Gairdner adduced, namely, (1) The progress of preventive medicine (2) The disappearance of orthodoxy (3) The cessation of the abuse of alcoholic stimulation in disease The paper though quite long was listened to with marked attention and was well received

The address in Surgery was delivered by Edward Hamilton M D, F R C S I, Prof of Surgery in the Royal College of Surgeons of Ireland, on, "*Tissue Resistance and Antisepticism*" The whole of this able paper would have to be given in order to appreciate its important and valuable contents, which is impossible now

The address in Public Medicine was given by the Rev Samuel Haughton, M D, Senior Fellow, Trinity College, Dublin, on, "*Reflections on Death rate, with Special Reference to Dublin and its Suburbs*" This was the most spicy and entertaining address delivered during the meeting The solid important facts were frequently interspersed with the best Irish wit The death rate of Dublin is very high, ranging from 22 33 in July to 37 13 in March per 1000 This is owing to the great number of poor people who are crowded together in certain districts Dr Haughton showed that a change in temperature from 50° to 32° increased the death rate from 35 4 to 44 3 per 1,000 "What this means no one can tell better than the clergy and physicians, who know the sufferings of the Dublin poor in winter The real cause of the high death rate in Dublin is the poverty of a large proportion of its inhabitants, which arises from causes quite beyond the control of the sanitary authorities How much of this poverty is due to political causes, and how much to the people themselves is no business of mine to discuss It is there and produces its deadly effects However, we must not despair, but by repeated efforts on the part of all, do what we can to relieve the sufferings of the poor, and remove their causes I would ask my Dublin friends always to keep in mind the answer of Simon Peter to the Divine Lord 'Master we have toiled all the night and taken nothing, nevertheless at Thy word I will let down the net'"

The social programme of the meeting was a prominent feature The *soiree* given by the President of the Association and the Dublin Branch at the Royal University of Ireland on Wednesday evening was a brilliant gathering attended by 3,000 people

Thursday morning a Breakfast was given to the members of the Association by the Irish Branch of the British Temperance Association The Annual Dinner occurred in the evening at 7 o'clock at the Royal University, and was attended by the Lord Lieutenant of Ireland, escorted by a famous Highland regiment The Liverpool Band furnished the music

On Friday, from 4 to 6, a Garden Party was given in the Fellow's garden, Trinity College, by the President and the Dublin Branch

On Friday night a conversazione was given to the members by Surgeon General Hassard and Officers of the Medical Staff in the Museum of Science and Art

Saturday was devoted to excursions which visited the Dublin Bay, the Water Works, Glendalough and Avoca, and the Boyne

Thus came to an end one of the most successful meetings in the history of the Association

W H H

Dublin, Aug 6, 1887

INTERNATIONAL CONGRESS

SECTION IV —OBSTETRICS

The following papers are announced

1 The Pathology and Treatment of Tubal Pregnancy, Mr Lawson Tait, F R C S, Birmingham, England

2 Tubal Pregnancy, J Veit, M D, Berlin

3 Operative Interference in Early Extra-Uterine Pregnancy, Michael O'Hara, M D, Philadelphia

4 The Alleviation of Pain during Parturition Professor P Zweifel, M D, Erlangen

5 The Normal Forceps, Professor Lazarewitch, M D, St Petersburg

6 The Origin and Causes of Sterility in Women, Luigi Casati, M D, Forli, 24 Via Bufalini

7 Cæsarean Section, Professor Leopold, M D, Dresden

8 Conservative Cæsarean Section, M Sanger, M D, Leipsic

9 In the Cases of Cæsarean Section, in which Porro's Operation is not Indicated, what is the Best Manner of Suturing the Uterine Wound? Domenico Peruzzi, M D, Bologna, Via Mazzini 22, Italy

10 The Prognosis of the Cæsarean Section, Professor William T Lusk, M D, New York

11 Porro's Operation, Goelson Duncan, M D, London, England

12 Embryotomy or Cæsarean Section? Ginlio Kirch, M D, Rignano Sull' Arno, Italy

13 Craniotomy on the Living Fœtus, Robert B Dixon, M D, Boston, Mass

14 Abdominal Section for the Removal of the Fœtus, Professor W H Wathen, M D, Louisville, Kentucky

15 A Study of Laparo Elytrotomy, Alexander S Clark, M D, Paris

16 On the Relation of the Atmosphere to Puerperal Fever, Joseph Kucher, M D, New York, N Y

17 The Prophylaxis of Puerperal Fever, Professor Emil Ehrendorfer, M D, Innsbruck

18 A Study of certain Questions in connection with Puerperal Fever, with Particular Reference to the Use of the Intra-Uterine Douche and Curette, Professor Charles Warrington Earle, M D, Chicago, Ill

19 Antiseptic Midwifery from the Point of View of a Rural Practitioner, W H Sharp, M D, Volcano, W Va

20 The Prevention of Puerperal Peritonitis, R Lowrey Sibbet, M D, Carlisle, Pa

21 On the Prevention and Treatment of Puerperal Fever, Morse Madden, M D, Dublin

22 The Treatment of Miscarriage, E Pasquali, M D, Via Condotti 9, Rome

23 Conservative Obstetrics, with especial reference to the Treatment of Abortion and the Third Stage of Labor, Professor Rodney Glisan, M D, Portland, Ore

24 The Kidney of Pregnancy, and its Obstetrical Significance, Professor A L S Gusserow, M D, Berlin

25 The Causes and Modus of Sudden Death in Eclampsia and its Prevention, A S v Mansfelde, Ashland, Neb

26 Puerperal Eclampsia, Ira E Oatman, M D, Sacramento, Cal

27 The Pernicious Vomiting of Pregnancy, Jacob Price, M D, West Chester, Pa

28 Vicarious Menstruation, Duncan C MacCallum, M D, M R C S, Eng, Montreal

29 A Study of Deventer's Method of Delivery of the After coming Head, John Bartlett, M D, Chicago, Ill

30 On the Contracted Pelvis in America, Robert Herdegen, M D, Milwaukee, Wis

31 The Necessity of Accurate Diagnosis of the various Malformations found in the Pelvis, Professor Wm S Stewart, M D, Philadelphia, Pa

32 The Treatment of Posterior-Occipital Positions with Special Reference to Manual Rectification, J Algernon Temple, M D, M R C S, Eng, Toronto

33 Maternal Impressions Affecting the Fœtus, W T Taylor, M D, Philadelphia, Pa

34 The Influence of Leukæmia on Pregnancy, Illustrated by a Case, J C Cameron, M D, 41 Belmont Park, Montreal

35 Lithiasis in Pregnancy, J E Kelly, M D, 16 East 29th St, New York, N Y

36 The Causes of Left Occipito Anterior Positions in Vertex Presentations, J W Atwood, M D, Burlington, Vt

37 Internal Uterine Hæmorrhage, the Result of Over distension of the Uterus from Hydramnion, Professor Edward Hy Trenholm, M D, Montreal

38 Relation of the Membranes to the Process of Parturition, Henry T Byford, M D, Chicago

39 Delayed Involution, Prof W H Byford, M D, Chicago

40 Development of the Placenta, H O Marcy, M D, Boston, Mass

41 The Histology of Reproduction, Middleton Michel M D, Charleston, S C

42 Dystocia from Rigidity of the Cervix and its Management, George Wheeler Jones, M D, Danville, Ill

Papers will also be read by the following gentlemen

Prof Gustav Braun, M D, Vienna
Professor A Carpentier, M D, Paris
L Ch Boishinière, M D, St Louis, Mo
J F Y Paine, M D, New Orleans
J Johnson Alloway, Montreal
E P Sale, M D, Aberdeen, Miss
E J Doering M D, Chicago
J Amédéee Doléris, M D, Paris
A Cordes, M D, Geneva
Thos Menees, M D, Nashville, Tenn
Rodrigues Dos Santos, M D, Rio de Janeiro
D Lloyd Roberts, M D, Manchester, England

Home Secretaries

SECTION VII, ON ANATOMY

The following is a list of papers proposed to be read in the Section on Anatomy

The Bladder, by Reginald Harrison, F R C S, etc, Liverpool, Eng

The Wolffian Bodies, by William Mitchell Banks, M D (Ed) F R C S, etc, Liverpool, Eng

A Paper (subject to be announced) by Prof E Frohmann, Jena, Germany

The Intercranial Nerve Tracts in the Light of Atrophy Methods of von Gudden, by E C Spitzka, M D, etc, New York

On the Development of the Torus Longitudinalis in Selosians and its Homology in Higher Vertebrates, by Prof Rabe Ruckard, M D, etc

On the Surgical Collateral Branch of each of the Main Arteries of the Human Body, by Edward Souchon, M D, New Orleans, La

A Contribution to the Pathology of Hip Disease, by Milton Josiah Roberts, M D, of New York

Anatomy of the Male Uretha and its relation to Stricture, by E R Palmer, M D, Louisville, Ky

Does a Relationship exist between Anomalies of the Visual Apparatus and the so called "Neuropathic Tendency," by A L Ranney, M D, New York

A Paper (subject to be announced) by Thomas G Morton, M D, Philadelphia, Pa

Compression Myelitis in Pott's Diseases, by George R Elliott, M D, New York

Anatomy of the Foot and its relation to the Operation of Tentomy, by Lewis Hall Sayre, M D, New York

Anatomy of the Bladder and its relation to Rupture, by I N Bloom, Louisville Ky

Dissection of a very Young Human Embryo, by Augustus C Bernays, St Louis, Mo

On the Urethra, by Reginald Harrison, F R C S, etc, Liverpool, Eng

Anatomy and Surgical Importance of the Renal Capsule and the Perirenal Adipose Tissue, by L H Dunning M D, etc, South Bend, Ind

Specimen, by W T Oppenheimer, M D, etc, Richmond, Va

The Didactic Teaching of Human Anatomy, by F W Langdon, M D, etc, Cincinnati, Ohio

A Contribution to the Pathology of Spinal Caries, by Milton Josiah Roberts, M D, etc, New York

Umbilical Cord, by C W Kelley, M D, etc, Louisville, Ky

Frozen Sections of the Male Pelvis showing relations of Peritoneum to Rectum, Blapder, and Median Line of Abdominal Wall, with special reference to

Supra Pubic Cystomy, by Albert B Strong, M D, Chicago, Ill

The Mesocephelon of the True Reptile, by E C Spitzka, M D, etc, New York

The Anatomy of the Rectum and its relation to Reflexes, by J M Matthews, M D, Louisville, Ky

Paper, title not announced, by L S McMurtry, M D, Danville, Ky

Studies in Brain Surgery, by Hal C Wyman, M D, Detroit, Mich

The Peritoneum and its relation to Injuries of the Bladder, by N B Carson, M D, St Louis, Mo

Contribution to the Pathology of Knee-Joint Disease, by Milton Josiah Roberts, M D, New York

The Groove of the Central Veins on the Inner Table of the Calvarium, by Frank R Fry, M D, etc, St Louis, Mo

Anatomical Considerations concerning the Application of Plaster of Paris Dressings to Fractures of the Femur, by W B Rogers, M D, etc, Memphis, Tenn

The Anatomy of the Urethra and Prostate Gland and Bladder, with special reference to Surgical Relief for Enlarged Prostate in Old Men, by Wm C Wile, M D, etc, Philadelphia, Pa

Presentation of Anatomical Specimen, by George Benjamin Johnson, M D, etc, Richmond, Va

Anatomical Points involved in Loss of Complete Scalp, including one Ear and greater portion of the Eyelids, by F C Schaefer, M D, etc, Chicago, Ill

The Colon, by S K Crawford, M D, Chicago, Ill

Anomalies of the Middle Thyroid Artery, with presentation of Specimen, by Max J Stern, M D, etc, Philadelphia, Pa

The Anatomy and Relations of the Cæcum and Vermiform Appendix with Special Reference to the Surgery of the Parts, by Hermann M Briggs, M D, etc, New York, N Y

On Comparison of Twenty Superior Maxillary Bones, by E M Wilson, M D, Bridgeport, Conn

The Destruction of Dissection Room Offal, by H C Boenning M D, etc, Philadelphia, Pa

Anatomical Points of Value in the Diagnosis and Treatment of Some of the Joint Affections, by N Stamm, M D, etc, Fremont, O

A Plea for some Reforms in the Present Methods of Teaching Anatomy, by Wm Perrion Nickson, M D, etc, Atlanta, Ga

The Anatomy of the Vermiform Appendix, with some of its Anomalies, by F M T McKennan, M D, etc, Pittsburg, Pa

The Proper Methods of Teaching Anatomy, by A P H Leuf, M D, etc, Philadelphia, Pa

Paper, title not announced, by Joseph Dickson, M D, etc, Pittsburg, Pa

Reports of Three Cases of Nephrectomy, with special reference to the Anatomy, by Geo Halley, M D, etc, Kansas City, Mo

The Anatomy of Stricture, by J Kneely Rhodes, M D, etc, Philadelphia, Pa

The Pivotal Point in Anatomy and the Principle Underlying It, by W H Triplet, M D, etc, Woodstock Va

WM H. PANCOAST, A M, M D,
President of Section

SECTION X—DISEASES OF CHILDREN

The Section will meet at 3 P M, Monday, September 5

The following papers will be read in the order named

1 An Investigation to Determine whether the Absence of Sewage and of Water Pollution diminishes the Prevalence and Severity of Diphtheria, by Dr Chas Warrington Earle, Chicago, Ill

2 Rate of Growth in American and British Children, and its Bearing on the Investigation of Diseases, by Prof W Stephenson, Aberdeen, Scotland

3 The Diseases of Faulty Habit, by Dr James F Goodhart, London, Eng

4 Deleterious Results in Children of a Narrow Prepuce and Preputial Adhesions, by Prof Lewis A Sayre, New York, N Y

The discussion will be opened by Prof W T Belfield, Chicago, Ill, and Dr DeForest Willard, Philadelphia, Pa

TUESDAY, A M, SEPTEMBER 6

1 The Milk Supply of the Cities Adulterations and Modes of Detecting Them, by Dr Cyrus Edson, New York, N Y

2 The Nutrition of Infants, by Prof Albert Leeds, Stevens Institute, Hoboken, N J

3 The Use of Cow's Milk in the Feeding of Infants, by Prof V C Vaughan University of Michigan, Ann Arbor, Mich

TUESDAY, P M, SEPTEMBER 6

1 Anatomical Characters of Membranous Croup as observed in Fatal Cases in the New York Foundling Asylum, by Dr W P Northrup, New York, N Y

2 Remarks on Tubage of the Glottis and the Manner in which it was Practised in France by Dr E Bouchut, Paris

3 Intubation of the Larynx, with Demonstration on the Living Subject, by Dr Joseph O'Dwyer and Dr Dillon Brown New York, N Y

4 Intubation versus Tracheotomy in the Treatment of Croup, by Prof F E Waxham, Chicago, Ill

WEDNESDAY, A M, SEPTEMBER 7

1 The Treatment of Strumous Glandular Enlargement of the Neck, by Dr Martin Oxley, Liverpool, Eng

2 Infantile Convulsions in Connection with After Neurotic Tendencies, by Dr J A Coutts, London, Eng

3 A Study of some of the Bacteria found in the Dejecta of Infants Affected with Summer Diarrhœa, by Dr W. D Booker, Baltimore, Md

WEDNESDAY, P M, SEPTEMBER 7

1 Hallucinations in Young Children, by Dr E Bouchut, Paris

2 Cerebral Irritation in Children, by Dr Jules Simon Paris

3 Treatment of Diphtheria by Antiseptic Sprays, by Dr Grancher, Paris

4 Treatment of Physiological Derangements in

Children due to Over Feeding, by Dr Cadet de Gassicourt, Paris

5 Notes on the Malaria of Children in Brazil, by Dr Moncorvo, Rio de Janeiro

THURSDAY, A M, SEPTEMBER 8

1 Observations regarding True Pneumonia in Children, by Prof A D'Espine, Geneva

2 Subject not announced, by Prof Oscar Wyss, Zurich, Switzerland

3 Some Observations on Headaches in Children and their Relation to Mental Training, by Dr W H Day, London

Discussion to be opened by Dr W S Dennett, Oculist, on Headaches in Children produced by Errors of Refraction

4 Scarlatina Nephritis from a Clinical and Pathological Standpoint, by Dr Henry Ashby, Manchester

Discussion to be opened by Frank Grauer, Pathologist, on the Pathology of Scarlatina Nephritis

THURSDAY, P M, SEPTEMBER 8

1 The Contagious Principle of Pertussis, by Prof Alfred Vogel, Munich

2 The Nature of Whooping Cough and its Antiseptic Treatment, by Dr Moncorvo, Rio de Janeiro

3 On Acetonuria in Children, by Dr Adolph Baginsky, Privadocent of the University of Berlin

4 Hereditary Syphilis and Rachitis in Brazil, by Dr Moncorvo, Rio de Janeiro

5 Marasmus, by Dr I N Love, St Louis, Mo

FRIDAY, A M, SEPTEMBER 9

1 The Treatment of Lateral Curvature, by Dr James Knight, New York

2 Anchylosis of the Knee Joint in a Straight Position by Excision as a Remedy for the Atrophy and Deformity following Acute Poliomyelitis of Childhood, by Dr Stephen Smith, New York

3 Hip Disease, Practical Points in its Treatment, by Dr A J Steele, St Louis

FRIDAY, P M, SEPTEMBER 9

Adjournment (optional) Mount Vernon Excursion Saturday

1 Forcible Correction of Contracted Knee Joint, by Dr E H Bradford, Boston

2 Progress of Orthopædic Surgery, by Dr Noble Smith, London

3 Section of Contracted Tissues essential before Mechanical Treatment can be Effectual, by Dr Lewis A Sayre, New York

4 The Scope and Limitations of Orthopædy, by Dr C Fayette Taylor, New York

---

EXCURSION TO THE CONGRESS

A meeting of St Louis phyicians, who will attend the Ninth International Congress, was held on Saturday, August 6th A committee was appointed to make arrangements for an Excursion to Washington, by which all the delegates from St Louis might go together It was also proposed that an invitation to join this Excursion be given to delegates of Missouri Illinois, Indiana, Kansas and Arkansas, and others who can start from St Louis The Excursion will leave St Louis Friday morning, September 2, at 8 o'clock, by the Ohio & Mississippi Railway This will enable the delegates from Illinois and Indiana to join the party during the day, and arrive at Cincinnati at night The next day the Excursion will pass the beautiful Cheat River country, the Alleghany Mountains, Cumberland Gap and Harper's Ferry, reaching Washington via the Baltimore & Ohio Railroad, at 1 15 P M, Saturday, giving ample time to make all arrangements before the meeting The party will be personally conducted by Mr G D Bacon, General Western Passenger Agent of the Ohio & Mississippi Railway Special rates have been secured and the best accommodations promised by the Company These rates and accommodations are also extended to members of the families of physicians who may go The committee recommend that all physicians who expect to attend, arrange to be in Washington not later than Saturday Those who desire to join this Excursion, please communicate at once with Mr Bacon, or with any of the committee State whether a through sleeper is desired

The committee further recommend that on account of the probably crowded condition of the places of registration, that members should register in advance, by sending ten dollars to Dr J M Toner, No 615 Louisiana Avenue Washington, D C Enclose a stamp for return receipt or ticket of registration This ticket of registration entitles you to the three (3) large volumes of proceedings, even though you should not attend A great many physicians from neighboring States have already written that they would join this excursion

I N LOVE, M D, Grand & Lindell Ave's,
J R LEMEN, M D, No 3217 Lucas Ave
Wm PORTER, M D, No 3137 Lucas Ave
St Louis, Mo *Committee*

LOCAL COMMITTEE OF ARRANGEMENTS —TO THE MEDICAL PROFESSION The Local Committee of Arrangements have the pleasure to announce to their American brethren that the widespread desire to attend the Congress is such that the amount of money for the reception and entertainment heretofore deemed sufficient will be entirely inadequate to provide for the large number that will be in attendance They are therefore constrained to appeal to their brethren throughout the country for additional subscriptions to the entertainment fund They feel that to their patriotic countrymen it is only necessary for the fact to be stated in order to secure the sending of such liberal contributions as will insure the entire success of the social features of this great international gathering on a scale commensurate with its dignity and importance Let all Americans come to the front, and insure to ALL the members the full measure of the hospitality of free America Contributions should be immediately forwarded to Dr C W Franzoni, member of the Finance Committee for the District of Columbia

By order of the
LOCAL COMMITTEE OF ARRANGEMENTS

DR GEORGE FIELDING BLANDFORD, 71 Grosvenor street, London, formerly Lecturer on Psychological Medicine at St George's Hospital, has promised to give a "General Address" before the International Medical Congress "On the Treatment of Recent Cases of Insanity in Asylums and in Private Houses" Dr Blandford occupies a high position among the psychologists of England, and his address will doubtless prove instructive

THE PROGRAMME OF THE GENERAL ADDRESSES before the Congress is understood to be as follows

Monday—Address by the President of the Congress, Dr Davis

Tuesday—Drs Flint, of New York, and Semmola, of Naples

Wednesday—Drs Unna, of Germany, and Blandford, of England

Thursday—Drs Lutaud, of Paris, and Neudorfer, of Vienna

Friday—Business meeting

Many of the Presidents of Sections will open their sessions by an appropriate address, and there is likely to be an *embarras de richesse*, as the worthy papers are apparently in excess of the time allotted the sessions for their reading and discussion

Committees of Reception for foreign delegates have been appointed in New York, Boston, Philadelphia, and Baltimore

MISCELLANEOUS.

RECOGNITION OF DENTAL GRADUATES —At the meeting of the Chicago Dental Club on June 27, 1887, the following was adopted

WHEREAS, At the last annual meeting of the American Medical Association, held in this city, a resolution was passed recognizing the graduates of all Dental Colleges which require a thorough course of instruction in all the fundamental sciences which underlie Medicine and Surgery, equal to the standard required by the best Medical Colleges of our land, as entitled to membership in in this Association with all its privileges, and

WHEREAS, Our honored friends, Drs N S Davis and W W Allport, of Chicago, were largely instrumental in bringing about this action of the Association and

WHEREAS, Both of these gentlemen have always taken an active interest in promoting higher education among dentists, and were also largely instrumental in the establishment of Dental Chairs in the Medical Colleges of our city, and the Section of Dental and Oval Surgery in the International Medical Congress, therefore, be it

Resolved, That we, the members of the Chicago Dental Club, express our appreciation of their untiring efforts and devotion to the cause of higher professional education, and the elevation of our "specialty" to the position which its scientific attainments deserve

JOHN S MARSHALL,
A E BALDWIN,
J AUSTIN DUNN

HEALTH IN MICHIGAN, JULY, 1887 —For the month of July, 1887, compared with the preceding month the reports indicate that diarrhœa, cholera morbus, cholera infantum and dysentery increased, and that rheumatism, influenza, neuralgia, bronchitis, pneumonia and tonsilitis decreased in prevalence Compared with the preceding month the temperature in the month of July, 1887, was higher, the absolute humidity was more, the relative humidity was less, the day ozone was about the same and the night ozone was less Compared with the average for the month of July in the nine years, 1879–1887, cholera morbus, cholera infantum and diarrhœa were more prevalent, and intermittent fever, consumption of lungs, remittent fever, scarlet fever and diphtheria were less prevalent in July, 1887

Including reports by regular observers and others diphtheria was reported present in Michigan in the month of July, 1887, at thirty six places, scarlet fever at twenty five places, measles at twenty seven places, typhoid fever at sixteen places, typhus fever at one place

Reports from all sources show diphtheria reported at three places less, scarlet fever at twenty four places less, typhoid fever at four places more, measles at nine places less, small pox at one place less and typhus fever at the same number of places in the month of July, 1887, as in the preceding month

SOUTH MICHIGAN MEDICAL ASSOCIATION —At its annual meeting, held in Adrian, July 12 1887, the following officers were elected for the ensuing year President, Dr D H Wood, of Quincy, Vice President, Dr J F Jenkins, of Tecumseh, Treasurer, Dr M P Malden, Tecumseh, Secretary, Dr B Whelan, Hillsdale

DINNER TO FOREIGN MEDICAL EDITORS —The Association of American Medical Editors will give a banquet to distinguished medical editors from abroad on Monday, September 5, 1887, at 10 o'clock P M, at the Riggs House, Washington, D C

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 6 1887, TO AUGUST 12, 1887

Major J C McKee, Surgeon, ordered for duty at Watertown Arsenal, Mass S O 181, A G O, August 6, 1887

Major H E Brown, Surgeon, sick leave extended to August 6, 1887, on account of sickness S O 184, A G O, August 10, 1887

Major P J A Cleary, Surgeon, ordered to Ft McDowell, A T, instead of Ft Assiniboine, M T S O 110, A G O, August 5, 1887

Capt Jno M Dickson, Asst Surgeon, died August 8, 1887 (station Ft Mason, Cal)

Capt J C Merrill Asst Surgeon, ordered from Ft Klamath, Ore, to Watervliet Arsenal, N Y S O 181, A G O, August 6, 1887

First Lieut Wm E Hopkins, Asst Surgeon, ordered from Angel Island, Cal, to Ft Mason, Cal S O 184, A G O, August 10 1887

First Lieut C N B Macauley, Asst Surgeon, promoted to be Asst Surgeon with the rank of Captain, by operation of law August 10, 7887

First Lieut J E Pilcher, Asst Surgeon, ordered from Ft Monroe, Va, to Ft Wood, New York Harbor S O 180, A G O, August 5, 1887

First Lieut C L G Anderson, Asst Surgeon (station, Whipple Bks, A T), ordered to Ft McDowell, A T S O 81, Dept Ariz, August 3, 1887

First Lieut Wm N Suter, Asst Surgeon, ordered to return to Washington Bks, D C, on the breaking up of the camp at Creedmoor, N Y S O 166, Div Atlantic, August 10, 1887

CORRIGENDA

In THE JOURNAL of Aug 13, p 193 col 1, 7th line, omit *posterior*

On p 195, column 1, 7th line read "thus will the perineum be *sacred*"

On p 196, paragraph beginning 'Dr Boisnière," begin to read with "Naegelé teaches" etc

In 4th line of that paragraph read *nevt in frequency* for "last in frequency" In 13th line of same read *these cases* for "his cases" In 14th line insert *or* after "flat" In 27th line read *placed* for "face" Omit last half of line 32 and first half of line 33

Page 196, 2d col, 7th line from bottom, read *insolation* for 'isolation'

Page 198, col 1, line 29, insert *such* before 'force" Same line 40, read *automatism* for "automation' Same p 2d col, 3d paragraph, for 'Yet, cases are reported" read "Yes cases are reported"

On p 199 summary of 1st table, read 'Of 24 known" etc Summary of 2d table, omit "not," and read 'Of 20 known 15" etc Summary of 3d table read 'Of 18 known," etc

Page 200 under 4, 2d col, 5th line, for 'new elements," read *nerve elements*

Page 204, col 2, under *Case 1*, 6th line, read "and the sight became very dim"

Page 206 22d and 23d lines of col 1, read *micro organisms* and *neuro retinitis*

ORIGINAL LECTURES

LECTURE ON THE TREATMENT OF TYPHOID FEVER

BY PROF DR HERMANN VON ZIEMSSEN,

DIRECTOR OF THE MEDICAL CLINIC IN MUNICH

Since typhoid fever was recognized as a disease *sui generis* it has always stood as the prototype of acute infectious diseases, and on that account it should be studied with especial diligence

After the anatomical nature of typhoid fever was determined in the first part of this century, and it was definitely separated from typhus fever, there was begun a reform in every way in the treatment of the disease The older of the now living physicians still remember the time of the so called indifferent therapy of typhoid of 30 to 45 years ago The brilliant results of the water treatment of typhoid fever (on Currie's precedent mostly by cold douches) were forgotten in the next decade, and again brought to light in the fifties With the introduction of the cold water treatment new life was given to the dietetic treatment of fever The care of the skin, for good bedding, for pure air in the room, for proper food and nursing of the patient, were the immediate results of the treatment by baths In the Prussian army Brand's method has reduced the mortality from 26 to 8 per cent Since Brand and Jurgensen published their first works on the subject the therapy of typhoid fever has been a constant object of the most zealous study, not only as regards hydropathy, but also in regard to pharmaco- and dieto-therapy The active treatment of typhoid fever, especially the bath treatment, has been more and more widely used in private practice, and it seems that after the important moderation in the energy of the cooling was introduced, the present active therapy of typhoid fever may be regarded as a valuable and permanent progress of therapeutics As between the extreme hydro therapeutists and those who would "rid the world of the water pest," I do not doubt that the true road to success in the cold water treatment of typhoid fever lies between the two extremes

Before entering into the details of the treatment of typhoid fever I will consider two cardinal objections to the active treatment of typhoid fever, which, if they correspond to the facts, are of great signification It has been recently claimed that in spite of the treatment the mortality of typhoid fever remains the same From this it would appear that the kind of treatment makes no difference in the ultimate result of cases of typhoid fever, and that the number of deaths in a single epidemic would be determined by factors beyond the power or control of treatment This stand point was taken by Port (*Archiv fur Hygiene*, Bd 81 u, 83) From the statistics of the Munich Garrison he draws the conclusion "Low ground water causes severe infection, high ground water light infection Treatment is without influence on the mortality, and of late years the low mortality has been due to the high ground water" But Vogl, who worked over the same material as Port, and from the clinical stand point (*Deutsches Archiv fur Klin Medicin*, Bd 36 u 37), showed that Port's conclusions were not supported by his material, and that the influence of a methodical cold water treatment in diminishing the mortality of typhoid fever is incontestable

The second objection was raised by Fiedler (*Jahresbericht der Gesellschaft fur Natur- und Heilkunde zu Dresden, 1883–1884*) whether with the diminishing frequency of typhoid fever in Germany the disease had not changed in its character, whether typhoid fever had not become another and milder affection That the mortality of typhoid fever generally has considerably diminished is shown by the numerous statistics from the different German States, and this is true not only of the large and smaller cities but also of the low country As the cause of this one may, without violence to facts, consider the improved draining of the soil, the improvement in the dwellings, better drinking water, in short, general hygienic activity of the people, of families and of individuals In many places in Germany, as in England, the coincidence of decrease of typhoid fever with the completion of canalization is very striking It is not long since I showed in regard to the city of Munich that with the progress of drainage there was a gradual, and since the Spring of 1880 a a sudden decrease in the number of cases of typhoid fever, for which there could be found no other cause than the drainage of the city Analogous results have been shown in many other German and English cities The reverse is seen in the old condition of affairs in cities which have done little or nothing in the way of improving drainage

The question as to the change of character of typhoid is worthy of consideration The possibility of such a change of an infectious disease in the sense

[1] Translated by permission of author and publishers from advance sheets by Wm G Eggleston M D of Chicago

of a diminution of its infectious properties certainly cannot be disputed, as is shown by the history of epidemic diseases, and since by drainage of the cities the germs of infection are more and more withdrawn from the soil, and thus great epidemics are now more infrequent, it is certainly conceivable that the severity of the epidemic is also lessened, since experience shows that the general mortality has a certain relation to the morbidity But despite the diagram of Dr Port we cannot acknowledge any influence of the state of the soil water on the typhoid morbidity and mortality, after proper drainage has been made And when by proper drainage and hygienic measures on the part of the people generally and individuals the frequency of typhoid is lessened, and great epidemics are no more seen in the places made healthy, it is not proved thereby that the intensity of the infection in other cases is lessened It can certainly be said that of late years the cases of typhoid fever in this city which were neglected in regard to proper diet and baths in private houses during the first and second weeks, but were otherwise in good circumstances, and were then taken to the hospital, showed on admission the same severe type, the same complications, and the same decubitus as were seen in former severe epidemics Nor have our trials of an indifferent, *i e*, purely dietetic treatment, of typhoid without antipyretic treatment, which were made for the purpose of comparing the two methods, shown by their results that typhoid has become milder, or that it, as Fiedler reservedly expresses it, from a clinical and pathological anatomical view it has taken another form The variations which Fiedler adduces, such as the former appearance of roseola in the first week, possibly depend on local influences, at least we cannot affirm such an occurrence in Munich The same may be said in regard to the variations from Wunderlich's normal temperature cure of typhoid The laws of the temperature range which Wunderlich propounded for single cases are dogmas, which are scarcely true for half the cases, and we should not count every deviation from this "type" of temperature range as abnormal Bi-hourly taking of the temperature in typhoid has shown a good deal more than appeared from the former morning and evening measurements, as has been shown by Immerman and me (Kaltwasserbehandlung des Typhus, Leipzig, 1870) and Weil (Zur Pathologie und Therapie des Abdominaltyphus, Leipzig, 1885) The same is true of certain so called symptoms in measles and croupous pneumonia and angina the so called "typical" course of the temperature is not so frequent as the "atypical"

Finally, it may be said that the changes from the former course of typhoid are partly due to antipyretic treatment—the infrequency of decubitus, of furunculosis and other destructive processes of the skin, laryngeal ulcers, etc Nor has this method of treatment been without influence on relapses of typhoid Hence, from the observation of many thousand cases of the disease I must say that typhoid fever has certainly decreased in frequency, but its character has not changed

The decreased mortality of typhoid fever during the last twenty years is due to two factors 1 Important improvement in the dietetic treatment 2 The antipyretic anti infectious treatment It has been justly said that it is not right to attribute the results of the present methods of treatment solely to antipyretic measures, and that we should not undervalue the influence of the improvement in dietetics of typhoid fever Attentive nursing, careful regulation of the skin, rational feeding—these are factors of the greatest importance But it must be remembered that measures were called out, and first made possible by the antipyretic methods, and chiefly by the cold water treatment With the introduction of frequent baths and taking of temperature arose the necessity for trained nursing and care of the patient The improved care of the skin is the direct outcome of the baths, and the improvement in the appetite and the corresponding effects on the stomach and intestines are to be ascribed prominently to the baths It was seen that assimilable food could be given in large quantities, and that it could be assimilated, and that the oxydation of the albumen of the organism, so much increased by the fever, was less with the antifebrile treatment, and from these two facts appeared the important result that the body generally, as well as each individual organ, came out of the infectious process with less damage than formerly, and that the patient's ability to work was restored more quickly than by the former indifferent treatment Rightly has Vogl said that it is not enough to know that the patient has escaped from the infection, but we should also know in what condition the whole organism and each particular organ has come out from the disease The question as to the amount of damage, and in how far antipyretic treatment can prevent this damage, can only be determined by continual determinations of the loss of weight, the duration of the inability to work, and an analysis of the convalescence under the different methods of treatment Vogl has already shown by a series of cases that by his method of strict water treatment the loss of weight is only about twice as great as in croupous pneumonia, and that after the conclusion of the emaciating period, which is 24 days in typhoid and 10 days in pneumonia, the period of return to the old weight is 17 days in typhoid and 18 in pneumonia This is certainly strong evidence in favor of the strict antipyretic treatment, and so much the more so as the material for observation in these cases (soldiers) was much more favorable for exact comparison, on account of similarity of constitution, than in civil hospitals

There are many skeptics to whom these facts will not be proof, the stock answer of these doubters is "You can prove anything by statistics" But it is seen that the authors who dispute the value of statistics use them for their one sided views Observation at the bed side shows the value of the antifebrile anti infectious method of treatment

I have already shown you at the bed side the different methods of treating typhoid fever I have shown you cases in which in spite of the severity of the symptoms and the height of the fever only a purely dietetic treatment was used On the other

hand you have seen cases of equal intensity of infection which were treated by moderately cooling hydrotherapy and antipyretic drugs In this way you have had the opportunity of seeing how continually high was the fever under the purely dietetic treatment, how severely the brain was affected, how great the muscular weakness, and how various the incidental symptoms In patients treated antipyretically, on the other hand, you have seen after the bath often marked reduction of temperature, moderation of the pulse and respiratory movements, restful sleep, and, especially, immediately after the bath free sensorium, clear vision, a fresh countenance, greater muscular strength, a longing for food The difference is most clearly shown by the cases which come into the hospital in the second or third week, after a so called indifferent treatment up to this time These people are usually in tolerably good circumstances, working people, artisans, students, and are the most severe cases, they show most clearly how important is a methodical treatment from the beginning of the disease, and how the prognosis is rendered worse the later the patient comes under such methodical treatment Liebermeister and Hagenbach have pointed out these facts in their excellent work on the use of cold water in febrile diseases, and I cannot sufficiently emphasize their importance Do not mistake my meaning I do not claim that a patient cannot receive in private practice the same methodical treatment as in the hospital, on the other hand, there are many factors that obtain in private practice that are more favorable than in a hospital, such as food, care and nursing By the above remarks I mean cases in which lonely young people who cannot get such attention, baths, ventilation, change of bed, etc, as they should have during the first weeks of the disease Such patients present the most severe type of typhoid fever, with all the secondary symptoms and complications that we were in the habit of seeing ten years ago and more in the majority of cases

We will first consider the dietetic treatment, in its widest sense, which has to do not only with the feeding of the patient but also with the nursing and care, the bedding, ventilation, moving, and psychical and intellectual activity of the patient To begin the methodical treatment of a case of typhoid fever there must be an appropriate room for the patient and a trained nurse, male or female

An appropriate sick room for the patient should be quiet, if possible not opening on the street, roomy and easily ventilated, and so much the better if a small room adjoins in which baths can be given It is absolutely essential that quiet reign in the room and in the immediate surroundings, unless this be the case the irritable nervous system is still more irritated by the continual noise In cities, however, these conditions are hard to fulfil, but we can demand that the largest and otherwise most suitable room in the house be used, and even that the "best room," the parlor, be given up to the patient It is important that there be a second bed in the room, standing near the patient's bed, to which the patient can be lifted when his bed is soiled or when it is otherwise necessary to arrange his own And a frequent change of beds is especially gratifying to the patient, it is very pleasant to be lifted from his hot bed and tumbled bed-linen to a fresh cool bed, and frequently it causes a half-hour's refreshing sleep

The care and nursing of the patient must be entrusted to a trained nurse It is one of the most important points in the treatment that there be correct, reliable and uniformly quiet nursing, that the temperature be taken by a skillful hand, that the baths, the cleansing, the feeding, the administration of medicines, etc, be all punctually and quietly done, and that this should be done day and night Nursing of the patient by female relatives is to be advised against, as decidedly objectionable from the standpoint of the physician They are too much interested in the case, disturb him, ask questions, and rob him of rest He should have complete physical and bodily rest, and not have his attention called to his surroundings Nor should the patient have visitors—not even his most intimate friends Until far advanced in convalesence there should be no visitors, no conversation, no intellectual activity or excitement The nervous system and heart are extremely exhaustible, and any exertion of the mind, any agitation of the heart may cause bad results

In all cases the patient must be absolutely prohibited from moving himself or getting out of bed, even to go to stool, or from one bed to the other It is not infrequent that patients in late stages of typhoid fever, in attempting sudden muscular action, such as standing, die suddenly from heart paralysis due to suddenly increased blood pressure So, too, emboli of the pulmonary arteries, by sudden dislodgment of autochthonous heart thrombi, may be caused in this way And not less dangerous are such bodily movements for the ulcerated and meteorismic intestine, which may be ruptured by sudden compression of the contracting abdominal and psoas muscles The patient should be lifted from one bed to the other, and should pass his urine and fæces while lying down, or held in a half upright position by the nurse

Especial attention should be given to the ventilation of the sick room When the weather permits the upper window in the room should be open day and night In winter the room should be thoroughly aired at least three or four times daily

The greatest order and cleanliness should prevail in the sick room, and everything which can cause uncleanliness or smell should be removed

It is the duty of the nurse to record regularly the temperature (two or three times hourly), frequency of the pulse, of respiration, frequency and quality of the stools, etc The physician can then, at each visit, see the condition during the last few hours by a glance at the record

A water mattrass as long and wide as the bed is indispensable in severe cases for the prevention of bedsores When it is properly filled the patient rests very easy upon it, with no pressure on the sacrum It should be so filled that the patient's body, by reason of its weight, does not press on the bottom of the mattrass, and that there are no air bubbles in the mattrass The physician should see to this, as the best nurses cannot always be depended on Some of

these seem to be small matters, but the smallest matters may be very important for the well being of the patient The round air-pillows found in many families should not be used, as the very thing that we wish to avoid, circulatory troubles from pressure, will be produced by these things along the whole circumference of the soft parts pressed into the ring One day's use of such apparatus will produce a cyanotic condition of the skin

The back, and other parts of the patient upon which he lies, should be rubbed once or twice daily with spirituous solutions, such as weak warm rum, Cologne water, etc They not only improve the subjective feeling of the patient, but also excite the circulation of the parts pressed upon and at the same time act well upon the nervous system through the organs of smell Any one who has ever been in such a condition knows how much these little things add to the comfort of the patient

We now come to the most important part of the treatment of typhoid fever—the feeding of the patient Thirty years ago oat and barley water was the only food allowed in *febris nervosa*, as typhoid fever was then called, wine was allowed in convalescence, but not during the febrile period Then came a time when albuminous food was forbidden on the ground that it would be but adding oil to fire A change for the better came from England, where fluid albuminous food and stimulants, especially alcoholics, were given from the beginning of the disease, and the German physician was accused of keeping his typhoid fever patient hungry At first the German physicians were very cautious with albuminous and alcoholic foods, but it was soon shown that under better feeding the patient withstood the disease much more easily, that less strength and flesh were lost, the convalescence was more rapid, and that less time was lost from work The experiments of Jos Bauer, Kunstle and H von Hosslin, made at the Munich Clinical Institute, and which showed that on the one hand the fever was not increased by giving fluid albuminous food and alcohol, and that on the other hand a large part of the nitrogenous food was absorbed in spite of the fever and diarrhœa, that it was of benefit to the organism, and that at all events the consumption of the albumen of the body was limited—these researches did much to naturalize a methodical good feeding in Germany Of course no pure albuminous food is given, and still less fatty food We must adhere as closely as possible to the normal proportions of food stuffs for the healthy organism as given by Voit, with the special consideration that fats are taken with difficulty by fever patients, best in milk, and that the carbo hydrates are not only best taken and best borne, but that they markedly limit the consumption of the albuminous and fatty matters of the body

Especial consideration must also be given to the changes and variety in taste and in the consistence of the food Nothing is so repugnant to the normal appetite and stomach as sameness in form and kind of food, and the typhoid fever patient is, possibly on account of his small appetite and weakened digestion, still more sensitive to sameness of diet Careful attention should therefore be given to variety of fluid food I say "fluid food," because solid and pudding-like foods cannot be given on account of the condition of the ileum, the ulcers of which might be irritated or ruptured

A large variety of preparations can be made from the carbo hydrates Starch, dextrin and sugar may be given in various forms, both in soup and drink, they are used through the whole course of the disease in mucilaginous soups Oat and barley water, as thin as possible, is to be recommended as drink, by the addition of sugar, cinnamon or wine, etc , variety may be given to the taste Then there are the manifold compounds of starchy and meat soups These should all be strained, and solid particles removed from them Clear meat broth, with or without yolk of egg, meat extracts, etc , are also recommended The meat broths must supply the necessary fatty food, as also the butter added to the soups and the milk Milk is the most complete mixture of albumen, fat and carbo hydrates, and is an excellent food in typhoid fever, but too much of it will cause uneasiness in the stomach Unfortunately, too, many persons cannot take it at all Usually I do not give more than one pint in 24 hours

In regard to other albuminous food I especially recommend freshly expressed meat juice, which, in so far as concerns digestibility, is preferable to eggs, etc In our hospital 15 or 20 pounds of beef are cut in pieces as large as the hand, a piece of linen cloth placed between each two pieces, and the whole put into the meat press (Reulaux's) The juice which escapes from the press consists of serum, lymph and blood, it is placed in a porcelain vessel and used as needed The reaction of the juice is generally slightly acid when it comes from the press, it must therefore be placed on ice, and should be prepared fresh every 24 hours About 150 or 200 grams should be used during 24 hours As, according to Voit and Bauer, this juice contains 6 per cent of albumen, the consumption of albumen during the day would thus be from 9 to 12 grams It should be given partly in teaspoonfuls, as medicine, and partly in the soup (2 tablespoonfuls to the cup) The soup should not be over 46° C (114 8° F), because the albumen of the juice would be coagulated, and if the broth is too hot it must be cooled before the juice is added For cases in which all food is rejected by the stomach Dr Ludwig, Physician to the German Hospital in London, uses a frozen meat juice which is well retained Meat juice is preferable to egg albumen and yolk of egg as a food on account of its greater digestibility, and on account of the fact that a patient will take it for weeks without repugnance, whereas he would soon refuse the daily use of egg albumen In further favor of meat juice is the fact that it does not cause the slightest digestive troubles, such as eructations, gastric oppression, or flatulence in typhoid fever I have used it daily for twelve years, in thousands of cases, not only of typhoid fever but of other diseases, and can recommend it most highly The meat preparations of Kochs and Kemmerich, as well as the Rosenthal Leube meat solution, are also to be recommended, but the taste of these prepara

tions often causes eructations, and prevents their use for any length of time, which is not the case with expressed meat juice Meat extract should be added to broths and soup in small quantity from the beginning of treatment, not merely on account of the taste, but as a stimulant to the nervous system No more than a small quantity on the end of a knife should be used to the cupful of soup, so that the taste may not be too pronounced

The addition of yolk of egg to the soup easily becomes repugnant to the patient, causing eructations and abdominal uneasiness As a rule, more than three eggs during the day should not be used, though account must be taken of individual digestibility and idiosyncrasies A very judicious combination is yolk of egg with brandy, in the form of Stokes's brandy and egg mixture The addition of butter to the soup improves its taste as well as its quality as a food, as is true of the addition of salt

I use wine from the beginning of the disease in the form of light non acid white or red wines, about a pint a day According to my experience the often used red wine cold in active intestinal symptoms (profuse diarrhœa, meteorism) is not favorable, but when it is warm, in the form of mulled wine (half a pint of red wine cooked with cloves, cinnamon and sugar), has an excellent effect on the diarrhœa and meteorism, so, too, tea with rum, grog made of good cognac, and taken not too hot I also use cognac regularly in the form of Stokes's brandy and egg mixture as medicine, a tablespoonful every two hours It consists of the yolk of two eggs, cognac 50, cinnamon water 150, simple syrup 30 grams The taste is exceedingly pleasant

It will be seen that our typhoid diet contains a tolerably large quantity of albumen, fat and carbo hydrates, though the albuminous matters are in proportionately larger quantities than the carbo hydrates, as compared with the usual health diet Renk calculated that in my clinic the proportion in the daily diet of a typhoid fever patient, which the patient easily took, was 91 parts of albumen, 78 of fat, and 100 of carbo hydrates In his typhoid fever diet at the Munich Military Hospital Vogl uses a proportion of 60 of albumen, 45 of fat, and 200 of carbo hydrates, and this is nearer to the proportion for the healthy man, which Voit places at 85 albumen, 30 fat, and 300 carbo hydrates, and Forster for the non-working public dependents at 67 albumen, 38 fat, and 266 carbo hydrates On account of the consumption of organic albumen in typhoid fever the amount of albuminous food must be proportionately larger The researches of H von Hosslin and Vogl show in the most unmistakable manner that organic consumption is limited by such diet, and that the duration of convalescence is shortened

The preparations of lime are also useful, as the lime can preserve a large part of the albumen from decomposition (Voit, Senator) They may be used in the form of jellies, best prepared from fresh calves' feet with white wine On account of their refreshing and pure taste they are very grateful to the patients, and may be given as a kind of cordial between other meal times

It need scarcely be said that the energy of the feeding and the use of stimulants should correspond with the intensity of the disease, in a mild case, with a good constitution and moderate fever, it is not necessary to feed with the same energy as in a severe case with high fever, weak heart and considerable local lesion in the ileum But it is advisable at the beginning of each case, even the mildest, to regard it as one which in the second or third week may become severe, and on this account the organic consumption must be prevented as much as possible by good feeding But as a rule, the feeding and stimulants should be proportioned to the disease

A diet table should be made out for the 24 hours, so that the attendants may follow it punctually and exactly, and thus the food and stimulants will be given at the right time As a rule it is advisable, in severe cases, to give food every two hours, and drink (barley water, wine) and medicine between meal times In this way the whole quantity of fluid food can be given, and the necessary variety given The patient should be fed at night as well as during the day, but in mild cases consideration must be had for the patient if asleep But in severe cases the two hour rule must be rigidly adhered to

In regard to the diet of convalescence, it is well to follow the usual diet of health, though somewhat modified, but from the beginning of convalescence, that is from the first feverless day, I order fluid diet (except that biscuit may be soaked in the fluid food) for five days This may savor somewhat of routine, especially to those who allow solid food during the whole course of the disease, but I recommend this nevertheless The return to solid food should be as follows First breakfast, tea with biscuit, one soft-boiled egg, second breakfast, 100 grams of finely minced raw bacon with wheat bread crumbs Noon, 150 grams of pigeon, young chicken, partridge, finely minced in soup, later with a mild sauce and a tablespoonful of *puree* of potato (prepared with milk), with wine or export beer Afternoon, tea with biscuit or cakes Supper, mush and milk, two soft-boiled eggs, some raw bacon This may soon be followed by calves' feet for breakfast, then an English broiled beefsteak or cotelettes of mutton with compote, and in the evening strengthening soup and some beer At this stage, when the patient thinks of nothing but eating, something new in the way of food must be given daily This is less the business of the physician than of the cook, but the physician should see to it that the food is properly prepared and digestible Fruit jellies and compotes, as of pears and apples, are very grateful now, as also wine and calves foot jelly, and rice meal or grits well cooked, etc Raw fruit is not without danger, and is best withheld during the first three or six weeks after the decline of fever, especially as cooked fruit in the form of compotes may be allowed in small quantities every day It is very pleasant for the patient to have something between meals to prevent his feeling hungry, a cup of meat broth or wine jelly, a soft boiled egg, a few oysters, or some caviar with butter and wheaten bread, and a glass of Madeira or Chablis may be given *(To be concluded)*

PATHOLOGY, DIAGNOSIS AND TREATMENT OF PERFORATION OF THE APPENDIX VERMIFORMIS

Read in the Section on Surgery at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J McF GASTON, M D

PROFESSOR OF SURGERY, SOUTHERN MEDICAL COLLEGE, ATLANTA, GA

Lest the title of my paper should lead to the impression that I have made observations of a practical nature on this grave condition, calculated to serve as a guide to the practitioner, let me announce at the outset that my inquiry is directed to the discussing of means for the clearing away of the doubts that cluster around perforation of the vermiform appendage

It is highly probable that many of the cases which run the ordinary course of typhlitis may originate in a slight yielding of the coats of the appendix, that allows an exudation of its contents and sets up a local inflammation in the neighboring tissues, with a shutting in of the pus by adhesive inflammation between the serous membranes around Such cases having the effects confined to a limited area of the abdominal cavity do not present the phenomena of general peritonitis, but retain the characteristics of a circumscribed inflammation

Having treated of the "Surgical Relations of the Ileo cæcal Region" in a paper laid before this body at its last meeting, and having contributed a paper on the "Surgery of the Ileo cæcal Connections" to the October, 1886, number of *Gaillard's Medical Journal*, I must presume upon an acquaintance with the points therein presented My attention will therefore be confined to the peculiar phenomena connected with perforation of the vermiform appendage, so far as they are capable of being considered separately from other forms of intestinal perforation, and peritoneal inflammation from other causes

The anatomical seat of the disorder is so definitely fixed in its commencement, that it would seem a simple matter to diagnosticate the origin of the symptoms, yet practically it proves a most difficult thing to differentiate the train of disorders associated with this accident from those troubles growing out of derangements in the ileo cæcal region from other causes The sympathetic disturbance in the abdominal viscera from local lesions are very obscure, and it is observed that in strangulated hernia, for instance, the pain is not located at the constriction but at the umbilicus In the case of strangulated inguinal hernia for which Dr N B Carson practiced resection successfully, it is stated, that "while skating, the patient was suddenly seized with a severe pain in the abdomen, which he did not locate definitely" Other instances might be cited in illustration of the absence of local symptoms in acute cases of obstruction of the bowels, and the history of the local origin of general peritonitis from perforation of the intestines, rarely presents an indication of the point at which it has occurred The same is observed in the early manifestations from perforation of the appendix Dr J D Bryant's fatal case of perforation of the vermiform appendix, exhibits strikingly the want of those local symptoms which might serve as a guide to the nature of the trouble at the outset He states that the patient has been suddenly attacked with a moderately severe griping pain in the epigastric region He noticed no pain or tenderness in the right iliac region About fifteen hours afterward, the pain became more severe than at the outset, and was still located in the epigastric region The tenderness on pressure was general, but was best marked, however, at the lower portion of the abdomen No isolated point of extra tenderness was discovered All pain was referred to the epigastric region, the same as at the outset of the attack

In the case reported by Dr Tiffany and in two of my own cases there has been a feature which has not been noted by others so far as I have observed, the pain in the privates If it should turn out that this is present in any considerable proportion of the cases of perforation of the vermiform appendage, it would prove an important element in the diagnosis It is difficult to trace any sympathy between the inflammatory process which accompanies the exudation from this particular locality, and the genital organs, nor does it appear that there is any influence that could be operative in perforation of the appendix rather than in typhlitis But the fact of pain in a marked degree being present in these three cases, which were verified as cases of perforation of the appendix, stands forth as an indication which may lead to some practical inference in making up the differential diagnosis of this condition It is desirable that other observers should direct their attention to this point in the early stage of trouble in the cæcal region, and report upon its presence or absence when the subsequent progress of the cases confirms the reality of this affection

This occurrence would seem to be more frequent in later years, if the fact of its existence formerly has not been overlooked in its effects being confounded with peritonitis from other local lesions It is evident that some of the cases are only brought to light upon a necropsy being instituted, and the profession now very properly insists on such examinations in obscure cases Unfortunately, the people are not educated up to the point of assenting to a proposition by the medical attendant to open up a body for the good of others and the promotion of science, and we often have difficulties to encounter in securing a post mortem examination of a patient But perseverance will generally be rewarded by the consent of friends having a fair measure of intelligence, and the insuperable prejudices of ignorant people can sometimes be set aside by using means of preventing decomposition along with the exploration under the plea of embalming the body It is, at the present stage of the history of abdominal disorders, so important to make autopsies in obscure cases that I would urge upon the profession accurate record of every symptom in cases of suspected perforation of the vermiform appendage, and in fatal cases all the details of the post mortem observations

I had an opportunity recently of making post-mortem examinations in two cases of perforation of the appendix, which were reported in the *Medical and Surgical Reporter*, of February 5 and April 20, 1887 In both of these patients the symptoms indicated trouble in the ileo cæcal region at an early period, but the location of the pain and tenderness on pressure was not limited in such form as to indicate the origin of the inflammation, and I am forcibly impressed with the difficulties attending any precise diagnosis of perforation of the appendix vermiformis before the disease has progressed so far as to render operative measures of little avail The double process of cutting down in the iliac region, and subsequently resorting to laparotomy, for the relief of cases attended with general peritonitis, has not been attended with satisfactory results, so that it behooves us, if possible, to go over the whole ground anew to discover some criterion for our guidance in such cases An occurrence of inflammation in the tissues of the cæcum, constituting typhlitis, from some accumulation within its cavity, may be relieved by evacuating its contents, and thus terminate by resolution, but it is very rare, if ever, that extravasation of fæcal matter in ulceration of the cæcum is not followed by a discharge in one or another direction It is therefore recognized by those of most practical experience as proper, at an early stage of inflammatory development in the vicinity of the cæcum, to make an exploratory puncture, to ascertain if there be any deep-seated focus of pus, and in the event such source of trouble is detected, a free incision, communicating with the hidden septic seat, is warranted

It is impracticable to determine the exact source of the suppuration, even when the opening at the bottom of this wound is large enough to admit the index finger for the purpose of exploration, and as a consequence the surgeon cannot decide generally, whether the lesion is in the cæcum or appendix, when the fæcal odor leads to the unmistakable inference of the escape of the intestinal contents As a rule, based upon the anatomical relations of the serous investment of these parts, any discharge through a perforation in either enters the peritoneum, and yet, by adhesive inflammation, may be confined to the immediate proximity of its escape, and hence produce a circumscribed abscess there On the other hand, when perforation of the vermiform appendix occurs, and the contents become diffused to a greater or less extent in the peritoneal cavity, the inflammatory action extends and constitutes general peritonitis with all its serious consequences, or may be partial from limitation by the surrounding adhesions between different layers of the peritoneum

We must seek an explanation of the train of disorders following perforation of the appendix in the irritating quality of the discharge from the opening, whether this be caused by the disintegration of tissue from a localized ulceration of the walls, or from the mechanical pressure of some foreign body or concretion within, which cuts its way through the structure into the peritoneum

There is present in the appendix at all times either fluid or solid fæcal matter, which escapes whenever an outlet exists, and though the quantity may be small at the outset, it gradually increases, so as to permeate in different directions, and being a toxic irritant, it sets up inflammation wherever it comes in contact with the delicate serous membrane, and ultimately induces destruction of its vitality, so that it breaks down in a necrosed state This brings about the ordinary results of typhlitis, perityphlitis, paratyphlitis or general peritonitis, and the object of the surgeon is to arrest its progress at a point least detrimental to the patient

The propositions I would submit for consideration are *first*, the impracticability of making a differential diagnosis between perforation of the walls of the cæcum and those of the appendix, and *second*, that the treatment in its preliminary steps is very similar, so that the operative procedure does not imply a knowledge of which is involved in the given case in advance of its adoption

The pathological modifications of the tissues in contact with the exudations from either must be identical, on the principle that like causes produce like effects, and the extent of such structural changes depends upon the area involved in the permeation by septic matter It is a well ascertained fact that the contact of fæcal matter with any of the tissues of the body other than the mucous surface with which it is brought into close relations in passing through the intestines, causes rapid disintegration of structure, and propagates a hurtful influence to all the adjacent tissues, with a general depression of the vital powers A concise and yet comprehensive paper by Professor Beck, of University College, London, in Heath's "Dictionary of Practical Surgery," gives the characteristics accompanying perforation of the appendix vermiformis so satisfactorily that I will avail myself of it for a general outline of its concomitants

Perforation of the vermiform appendix is most commonly caused by the presence of a concretion or foreign body within it According to Dr Fenwick, who has collected and analyzed 129 published cases, amongst those in which the nature of the obstructing body is recorded 28 were concretions, 14 hardened fæces, and 5 foreign bodies Amongst the cases in which no concretion was found, tubercular ulceration seems to have been the most common cause of perforation, and a few occurred during or after typhoid fever Concretions are most common in males under 20 years of age In my two fatal cases referred to already, one, in a gentleman about 32 years old, resulted from a bean becoming impacted in the appendix immediately below its attachment to the cæcum The other, in a youth 10 years old, was caused by an oblong pointed fæcal concretion located about the middle of the appendix

The effects produced by perforation of the vermiform appendix vary with the anatomical relations of the part and the seat of the ulceration According to Mr F Treves the appendix commonly lies behind the end of the ileum and its mesentery, and is directed upwards and towards the left In the only other common position it ascends vertically behind the cæcum It may, however, be so placed that its

free end lies at the brim of the pelvis If perforation takes place near the attached end, or if the whole tube lies behind the cæcum, the abscess would be in the same situation as that resulting from diseases of the cæcum, and would be indistinguishable from it When the appendix occupies its more common situation, and when the perforation occurs in the free part, it is followed either by general peritonitis, usually fatal under a week, or by the formation of a collection of pus enclosed in a cavity formed by the surrounding coils of intestines firmly united to each other by adhesions According to Dr S Fenwick in 95 cases of which accurate details could be obtained, 38 presented localized collections of pus

Premonitory symptoms may be entirely wanting, but occasionally there is a history of obscure pains in the right iliac fossa or of periodic attacks indistinguishable from ordinary typhlitis

In the cases in which perforation is followed by diffuse peritonitis, there is usually a sudden invasion, often during some violent exertion The pain commences in the right iliac fossa, but soon extends to the whole abdomen There is constipation, distension of the abdomen, and absence of evident movement of the intestines The abdomen is tender, but most markedly in the the right iliac fossa, when some fullness may be felt The symptoms are much less severe than those of perforation of the stomach or other parts of the intestines, as the extention of the inflammation is less rapid owing to the absence of the abundant extravasation of the intestinal contents For the same reason collapse is not marked Vomiting, often of dark colored matter, is a marked symptom, as in all other forms of peritonitis

The symptoms of perforation with localized peritonitis are much more obscure The invasion is usually somewhat sudden There are localized pain and tenderness in the right iliac fossa The pain resembles colic in character There is usually constipation, but it may alternate with diarrhœa Vomiting is commonly present After a day or two an irregular, diffused, elastic swelling may be felt in the right iliac region At this time rigors are not uncommon, with temperature 103° to 104°, accompanying septicæmia General peritonitis with intense injection of the serous membrane, and adhesions of recent date between the different coils of intestines and the parietes of the abdomen exist Purulent fluid may be found localized by surrounding adhesions, or diffused in the peritoneal cavity

In the diffuse form the diagnosis from other forms of perforative peritonitis can only be made by the comparative absence of collapse, by the commencement of the pain in the right iliac fossa, by the tenderness in that region, and by the somewhat gradual extension of the inflammation to the peritoneum generally The localized form most closely resembles simple typhlitis, and sometimes can hardly be distinguished with certainty As a rule the swelling is more diffused and more acutely tender at an early period than in simple typhlitis, and the constitutional symptoms are much more marked, (Heath's Dictionary of Practical Surgery) An exploratory operation to discern the source of the disorder, or a post-mortem examination, are the only means of reaching a definite conclusion as to the precise nature of the case, and if we would avoid the latter the former must be resorted to at an early period

Until recently patients suffering from perforation of the vermiform appendix were practically left to die under the soothing influence of opium, when their end was not hastened by purgatives, enemata, and other violent measures There is, however, no doubt that whenever perforation takes place the only chance of life lies in opening the abdomen early and freely draining the cavity This is applicable to those cases in which there is general peritonitis, and still more so to those in which the mischief is localized, whenever a diagnosis can be made

The incision should as a rule be made above the outer part of Poupart's ligament, and should be about three inches in length The muscles should be carefully divided and the peritoneum freely opened The vermiform appendix should then be sought for, and, if it be found and is evidently diseased it may be ligatured with catgut and cut away If there is diffused peritonitis, with purulent fluid amongst the coils of the intestines, an attempt may be made to clean the cavity by means of sponges squeezed as dry as possible, after being soaked in some antiseptic solution, such as carbolic acid (1 40) corrosive sublimate (1 500) or tincture of iodine (ʒij to Oj) If the pus is distinctly localized in a cavity, it is better not to attempt to clean it out, for fear of breaking down the surrounding adhesions After the operation a large drainage tube should be inserted and the wound closed as far as possible by sutures The operation should be performed with antiseptic precautions, and some antiseptic dressing be applied

It may be necessary in some cases to modify the incision Should the swelling be situated near the middle line, Professor Beck says the abdomen might be opened at the outer border of the rectus muscle, but care must then be taken not to wound the epigastric artery He erronously claims that the middle line can seldom be a suitable situation for the incision, as, being so far removed from the seat of the disease, the drainage would not be efficient All who have had practical experience in laparotomy for inflammatory affections will doubtless differ with him in this, as the linea alba is now generally preferred for the incision, and by carrying it to a sufficient extent no difficulty is found in reaching any part, and in effecting drainage satisfactorily It devolves upon the operator likewise to resort to copious irrigation, with or without antiseptics, to remove all purulent collections from the cavity

In the debate upon penetrating wounds of the abdomen at St Louis I adverted to a simple process for detecting the presence of fæcal matter or blood in punctured or gun shot wounds, which is applicable for an explanatory operation in cases of suspected perforation of the vermiform appendix The report of my remarks will be found on page 596 of THE JOURNAL of November 27, 1886 They may be summarized by stating that the doubt as to existing lesions of the intestinal canal may be resolved usually by passing two tubes through an opening in the ab-

dominal wall at the site of the injury, both being of a length to reach throughout the cavity, with the outer end of one free and open, while the other is joined to a Davidson syringe The drainage tube should be fenestrated for some inches from the extremity that is within the abdomen, and the other end left entire outside to carry off the fluid injected, with whatever admixture it may contain, whether sanguineous, fæcal, or purulent A solution of common salt at a temperature of 100° F , may be thrown into the peritoneal cavity continuously, and allowed to pass out by the escape tube, until the water returns free from the abnormal ingredients therein contained If the outer termination of the syringe be then secured to the fenestrated tube, while the other is removed from the cavity, suction will remove the remaining fluid I am impressed with the advantages likely to be derived in diagnosticating the conditions resulting from perforation of the vermiform appendix first by aspiration, and subsequently by the process of irrigation here described, as it is evident that a flexible tube may reach accumulations not accessible to the straight or curved metallic tube ordinarily used with an aspirator The puncture made in aspirating would not suffice for the insertion of a tube, and it would therefore be requisite to make such an incision as to admit a single tube if suction only was indicated, or two tubes if irrigation was intended This incision should be no larger than necessary, and ought to be made in that part where the supposed exudation or suppuration could be reached most directly Such a proceeding is called for in the first instance as a means of diagnosis, but may become afterwards an important measure of treatment when a diffused inflammation in the abdominal cavity coexists with local conditions requiring the standard operation by an incision in the iliac regions Thus the grave complications of following the ordinary procedure in cases of typhilis by abdominal section may be averted, and the prospect of a favorable issue enhanced

The adoption of prompt and efficient operative measures in the early stages of that inflammation which is set up by perforations of the vermiform appendix depends upon a recognition of the conditions at the outset, and a resort to the exploring needle or the aspirator directly through the tissues involved is warranted by the practical result of those who have had the most satisfactory results in treating this class of cases, as well as in the various modifications of typhlitis If there is one thing more than another that is pressed upon our attention by the recent developments in abdominal surgery it is that delays are dangerous, and we must take time by the forelock if anything is to be accomplished in snatching from the jaws of death a patient who is suffering from perforation of the vermiform appendix I am so convinced of the urgent demand for surgical interference at the very earliest practicable period after the occurrence of this accident, that even in a case of simple typhlitis with symptoms causing no misgivings as to perforation, it strikes me forcibly that any cautious surgeon would be authorized in cutting down above Poupart's ligament to verify the true state of the deep seated structures If no lesion is found in either the cæcum or vermiform appendix, no serious trouble is likely to follow such incision, but on the contrary the drainage effected from the immediate neighborhood of the tissues involved in inflammation must prove beneficial, and the history of early incisions where pus has not been discovered encourages the surgeon to adopt this practice

Should it appear, on the other hand, that a perforation, however slight, exists either in the cæcum or vermiform appendix, the recourse to Lembert's suture for lesions of the cæcum, and of excision with ligation in perforations of the appendix, afford the best prospect of staying the progress of disorganization A thorough cleansing of the adjoining tissues by antiseptic washes, avoiding the solutions of bichloride of mercury, is likely to correct the disintegrating process set up by the septic contamination, and by the continuous use of iodoform with the dressings of absorbent cotton, a reasonable calculation may be made of saving the patient It is not incumbent upon the surgeon to wait for a certainty of perforation—but when a just ground of apprehension exists, he should operate and give his patient the benefit of the doubt

The practical deductions from this inquiry in regard to the concomitants of perforation of the appendix vermiformis may be included under the following heads

1 The primary disorder is dependent upon a local irritant, either mechanical, chemical or vital, inducing ulceration and disintegration at some point in its walls

2 The modification in the tissues of adjacent parts depends upon the presence of a toxic exudation from its cavity, that ultimately leads to disorganization of structure

3 Extension of the degenerating process depends upon the permeation of the structures with the fæcal matter, but may result from suppuration, or the automatic propagation of inflammation from one part to another

4 Agglutination between the layers of peritoneum may shut in purulent accumulations, and thus limit the inflammatory action to a circumscribed area, so as to assume the nature of an abscess in that locality

5 General peritonitis may be accompanied by extensive adhesions of the adjacent serous membranes, and followed by vital prostration and collapse, calling for the knife

6 Septicæmia may occur from absorption of septic matter independent of suppuration, and associated with a low form of fever which ought to be treated by antiseptics and irrigation of the abdominal cavity by hot water

7 When there are sufficient indications of perforation in the general symptoms, with pain and tenderness on pressure over the cæcal region, without signs of fluctuation, an exploratory puncture below the ileo cæcal junction is warranted

8 If there are any reasonable grounds to believe that pus is present, or that there is extravasation of fæcal matter, whether from the perforation of the

cæcum or appendix, a free incision above Poupart's ligament should be carried down to those parts and drainage kept up afterwards

9 In perforation of the appendix associated with general peritonitis an incision in the linea alba affords the best prospect of reaching all the parts involved, and should be accompanied by thorough cleansing of the abdominal cavity and especially of the ileo cæcal region

10 The most efficient means of closing an opening in the cæcum is by Lembert's suture, while an opening in the appendix demands excision and ligation

11 When perforation is suspected, washing out the abdomen by the use of a syringe and two tubes will assist in the diagnosis and treatment

12 An early operation with a doubtful diagnosis of perforation of the appendix lessens the likelihood for a confirmation of it by a necropsy, and hence no time should be lost in awaiting developments

---

THE CHIEF SOURCE OF DANGER IN THE USE OF THE UTERINE SOUND

Read in the Section on Obstetrics and Diseases of Women, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

BY GEO F FRENCH, A M, M D,

CLINICAL PROFESSOR OF GYNECOLOGY, MINNESOTA HOSPITAL COLLEGE, MINNEAPOLIS, MIN

It is the prevailing opinion of the medical profession that the principal danger to guard against in probing or sounding the uterus is traumatic lesion from incautious handling of the instrument This is also the teaching, positively or negatively, of nearly all the leading text-books on Gynecology, including those of such eminent authors as Emmet, Thomas, Goodell, Mundé, Hewitt and Courty

In the third edition of the "Principles and Practice of Gynæcology" Emmet says "Many a poor woman has endured years of bad health from the carelessness of her physician, in overlooking a latent cellulitis which became rekindled by the unskillful use of the probe or sound" Every student of this great master leaves his book with the impression that lesion from rough or incautious handling of the instrument is the danger chiefly to be borne in mind Conformably to this view, Dr E C Dudley, in his recent contribution to Pepper's "System of Medicine," conveys at once his own opinion on the subject as well as his impression of Emmet's teaching, that traumatism is *the* danger to be averted, by quoting him as to the dangerous use of the sound "from frequent lighting and relighting of pelvic inflammation *by injudicious slight manipulations*"

Writing on the same subject, Mundé says "The dangers attending the introduction of the sound are, the production of uterine colic or actual collapse from shock, a temporary affair, and of inflammatory reaction in the serous or cellular tissue of the pelvis

The precautions to be observed in using the uterine sound or probe, are chiefly comprised in the two words, *delicacy* and *gentleness*" In the English edition of Schroeder, which appeared in Ziemssen's "Cyclopædia," he says "As a rule I consider the sound harmless, provided it is employed by an experienced hand," but in the last German edition, 1886, he adds "If there is no abrasion of the mucous membrane *nor infectious matter on the sound*" In the fourth edition of Graily Hewitt's work on 'The Diseases of Women" there is not a word of caution, but the simple statement that "as a general rule, patients experience no inconvenience from the use of the sound if it be carefully introduced"

In the fifth edition of Thomas' classical work, "The Diseases of Women," the author himself expresses no definite opinion on this subject, but quotes Nonat and Scanzoni to show that for some reason sounding the uterus is very hazardous The former says "on account of the accidents which sounding may excite, it should only be resorted to with great caution and in those cases where its necessity is clearly shown" The latter, Thomas tells us, candidly acknowledges "that the uterine sound is by no means so harmless as has been asserted"

From Chrobak's contribution to Billroth's "Handbook of Diseases of Women" I extract the following "Since Broca in 1854 published the first case of death resulting from the introduction of the sound, the number of this class of cases, published, is quite large still larger the number where a slight or severe sickness (without fatal result) followed"

Now, when we consider the remarkable tolerance of the uterus of such surgical procedures as curetting, divulsing, not to mention accidental perforation, it appears to me that some more obvious cause must be found to account for the apprehensions expressed by the authors just quoted This prolific source of danger, comparatively unrecognized, lies I believe in septic matter conveyed into the uterine cavity by the non disinfected sound When we study the histological nature of the uterine cavity the danger becomes apparent We can all remember when traumatism was the bugbear which deterred us from entering the peritoneal cavity, and when, every now and then, a healthy patient succumbed to cystitis, (as the death certificate read) after merely being catheterized, we regarded it as due to traumatic shock But we have learned better I can myself recall many cases of grave cellulitis and peritonitis during the past twenty years, which, explained by traumatism, were unaccountably mysterious, but as due to septic infection, are painfully easy to comprehend Some surgeons like Mundé and Tait are so absolutely clean in their method of performing surgical work, no septic results occur, though apparently they ignore this principal source of danger and are conscious of guarding against traumatic lesion only Thus Mundé sounded the uterus five thousand times without a single catastrophe which only proves to my mind that Mundé practices better than he preaches A criticism equally true of the Pyo Salpingist of Birmingham

I would by no means detract one iota from the importance of delicate manipulation in exploring the the uterine cavity, but I maintain that the danger from traumatic lesion is completely overshadowed by

that from septic infection The enunciation by Nœggerath, in 1872, of the doctrine of latent gonorrhœa as a potent cause of pyo salpinx is but just now fully recognized, and instead of regarding Nœggerath's discovery as an isolated and exceptional fact, I believe it is one of a large group of facts illustrating a general principle

LeBec has investigated the course of the lymphatics of the upper portion of the vagina and cervix, and allege that they pass below and outside the base of the broad ligament to the obturator glands which communicates with the inguinal glands In the cervix the lymphatics of the mucous membrane are connected with the saccular sinuses extending near the epithelium of the inner surface of the mucous membrane (Lindgren) In the muscular layer we have lymph-vessels and lymph spaces, the lymph-vessels are most abundant in the external muscular layer and are connected with the lymph vessels of the mucous and serous layers and run into large valved canals at the side of the uterus Thus the lymph passes from the mucous membrane lymph spaces into the vessels and spaces of the muscular bundles up to the serous coat, and then passes into large tubes in the broad ligament Leopold considers the uterine mucous membrane as a lymphatic gland or lymphatic surface, intersected with glands and blood vessels, the lymphatics being not mere vessels but spaces between the connective tissue bundles

To the author of these anatomical researches, D Berry Hart, the collaborator of a clever work on Gynæcology, which he modestly styles a manual, belongs the distinction of being the first among English speaking writers to systematically call the attention of the profession to this still unappreciated danger We have, then, to look to Edinburgh for an advanced view like the following " The great dangers to the patient from the passage of the uterine sound, are abortion and abrasion of the mucous membrane, *with absorption of septic matter* and resulting cellulitis or peritonitis " Two cases of this nature are reported by Sanger, of Leipzic

It is manifest that a gonorrhœal pyo salpinx might be communicated as readily by an infected sound as by the extension of the disease from the vagina So too, a septic pyo salpinx, non gonorrhœal, whether derived from the virus of erysipelas, pyæmia, diphtheria or scarlet fever, may be carelessly transferred from the gynecologist's hand or sound, and give rise to a pelvic peritonitis with more or less systemic infection, such as has never been observed as the result of a gonorrhœal infection which is believed to limit itself to the mucous membrane Among the German authors Fritsch has done signal service to emphasize these dangers, and forcibly says "Always before introducing the uterine sound, dip it into a five per cent solution of carbolic acid, even though properly cleansed directly after its previous use "

Although these words belong to the New Testament of medical belief, and were uttered several years ago, the momentous truth inculcated is as slow of recognition and general acceptance as were the oracles of the inspired Semmelweis

DISCUSSION

Dr A Reeves Jackson, of Chicago I appreciate the invitation to address the Section upon this subject, but I find myself utterly unable to do so owing to the fact that I am just recovering from an attack of laryngitis I have been extremely interested in the paper and fully endorse the views given therein I think there is one source of danger in the use of the intra uterine sound that has not been mentioned, the attempt to make use of it as a placer in cases of displacement of the uterus I know from my own experience, when I was still more inexpert than I am now, that I attempted to do more with the sound than I would now do What I can now do better with my fingers I then attempted to do with the instrument I believe the author is right in attributing the source of danger to septicæmia in the way he has described The paper is a very excellent one, and is likely to lead to the best results

Dr E W Cushing, of Boston I think the thanks of the Section are due to Dr French for bringing up this important subject There is one particular which he did not dwell upon, that is that it is not merely the sound which carries the infection from some previous case, but that the vagina in itself is a hot bed for various kinds of bacterial growth Any one who will examine the discharge of the secretions of the uterus will find various kinds of bacteria and there is no doubt but that these bacteria will cause septic inflammation It seems to me that the sound is very apt to be innocent if reasonably well taken care of, but where great care is necessary is not only in disinfecting the sound but the vagina and the neck and mouth of the womb before the sound is introduced In hospital and private practice I invariably thoroughly irrigate the vagina with a bichloride solution, afterwards I cleanse off the mouth of the womb and then with a probe and carbolic acid cleanse out the cervical cavity before passing the sound into the womb With this precaution I have never had any trouble, and I do not think there is likely to be any except in cases of salpingitis, where the inflammatory action is already there or carried from the vagina into the womb

Dr C R Reed, of Middleport, Ohio No doubt it is true as stated that the vagina is a hot bed for the transmission of bacteria Then what is to hinder the bacteria at any time from traveling up the cervix through the Fallopian tubes and reaching the peritoneal cavity, they are so small that there would be no trouble in doing this When I use the sound I invariably use it through a speculum, so that it does not come in contact with the vaginal walls The paper of Dr French was a very able one, and one that teaches a practical lesson If the sound is dipped into very hot water or an antiseptic solution as suggested, I think it may just as readily be passed now as when Sims brought it into use forty years ago I have used it thousands of times, and I do not recall any instance in which I thought any inflammatory action followed the operation, but I take the precaution of invariably using it with the speculum or disinfectant

Dr W W Potter, of Buffalo, N Y I do not

wish to take up the time of the Section on this subject, but it is fair that I should express my appreciation of the paper of Dr French, because it follows out in a special way a line which I undertook to mark out in a more general way in this Section last year If we examine the literature of gynecology, both that which has been so easily cited from the text books by the author, and also the journalistic literature, we can but be impressed with the fact that there is a growing caution with reference to the use of this instrument, and it is a pretty general conclusion that observers have reached that it has done and is doing considerable hurt Whether it does it in one way or another may not be absolutely possible for us to determine But I have no doubt the author wishes to impress upon us that this is one, and perhaps the chief way in which the sound itself does harm Dr Cushing has mentioned the fact that the vagina is more or less loaded with bacteria or other germs which may be carried up by the passing of the sound through that tract even when the sound itself has been perfectly purified or sterilized before using I think there is something in that, and as these gentlemen have asked that the sound be rendered thoroughly antiseptic before using, let us also render the vagina so, let us precede the examination and treatment of the case by a thorough washing out of that cavity with an antiseptic solution

DR FRENCH said, in closing the discussion You will note that the subject of my paper was "The Chief Danger in the Use of the Uterine Sound" I tried to show that there is an alarming degree of danger which comes from the use of the sound, in some mysterious way I showed by records that injuries to the uterus by divulsing, etc, do not explain it I brought this subject before you because I think it is of importance, and no American text book touches upon it, yet I can show that it is a most prolific source of danger Gentlemen have said that the bacteria incident to the vagina are the prolific and almost as great a source of danger as that spoken of I demur, and for this reason We have demonstrated the fact that gonorrhœa produces pyosalpinx, we have also demonstrated the fact that there is a septic variety entirely distinct from this depending upon pyæmia, scarlet fever, etc In regard to the bacteria which exist in the vagina normally, it is a hypothetical view to take of the subject and the point is not proven, and while it remains a hypothetical question we have no right to consider it with the question of chief dangers in the use of the uterine sound

---

CLONIC RYTHMICAL SPASM OF THE PRONATOR RADII TERES

Read in the Section on Practice of Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association

BY HAROLD N MOYER, M D

LECTURER ON PHYSIOLOGY, RUSH MEDICAL COLLEGE INSTRUCTOR IN NERVOUS DISEASES, POST GRADUATE MEDICAL SCHOOL, CHICAGO

"There are few topics of more utility for the physician to study in our opinion, than that of monoplegias and mono spasms of hemiplegias and hemi spasms in their genesis, mutual relations, and diagnostic significance," says Seguin in his article on the general semeiology of nervous diseases, in the fifth volume of Pepper's "System of Medicine" A superficial examination of our standard text books, will show the paucity of information regarding hyperkinesis, except in so far as the symptom relates to the diagnosis of paralysis agitans, chorea or sclerosis A myoclonus limited to a single muscle, is not uncommon, and is usually observed in the ciliary, orbicularis palpebrarum, and masseter muscles The sterno cleido mastoid may also be affected with a clonic spasm, giving rise to one of the most painful forms of wry neck A case such as is here detailed of a clonic, rythmical spasm of a single muscle lasting nearly eight months without paralysis, contracture or atrophy has not until the present come under my observation, nor have I seen such described in any of the literature accessible to me

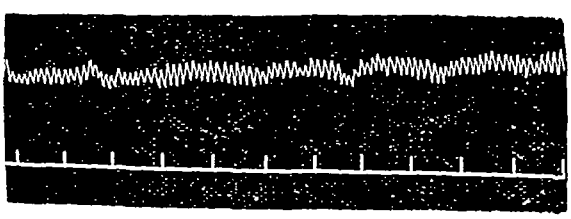
The history of the case is as follows

S C, school girl, age 17 years, of a healthy family, free from all hereditary neuroses Father and mother living and well, one brother died in infancy of some acute affection Patient is a slender but by no means delicate girl Began menstruating at the age of fifteen, and has never had any uterine or ovarian disturbance Gives no history of hysterical or "nervous" attacks Six months before present attack was troubled with an affection called, "gastric fever," by her physician, this was followed by some headache which was aggravated by anxiety over school examinations held at this time

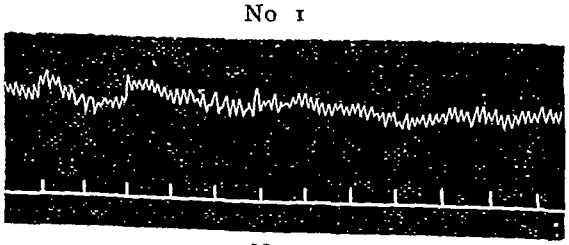
In October 1886, while sitting quietly at her desk in school, she suddenly felt her right arm jerking, she could not stop the spasm by any voluntary effort It continued the remainder of the day and the entire night The following afternoon, twenty four hours after the attack began, she presented herself at the clinic for nervous and mental diseases in Rush Medical College The pronator radii teres was found to be contracting rythmically about 120 times per minute Each contraction of the muscle pronated the hand, which as the muscle relaxed, immediately returned to a position a little short of midway between pronation and supination, when the next contraction again pronated the hand The movement exactly resembled voluntary pronation when performed as rapidly as possible If the hand was strongly supinated and held firmly considerable pain was felt in the muscle When the forearm was allowed to assume a natural position, no pain was felt, indeed the patient during the early part of the trouble never complained of any discomfort except a slight nervousness, due as she said, to the constant motion of the arm The muscle feels tense and cord like under the skin, but does not seem swollen No redness or any evidence of inflammatory reaction An effort was made to overcome the contractions by pressure on the median nerve, constricting the arm with a band, and fixing it firmly These measures did not diminish or prevent the spasm in the slightest degree Electricity

in the form of constant current was recommended She was treated for the next four months by her family physician with an ordinary interrupted current from a revolving dynamo machine, each application was attended with considerable pain For a month the contractions continued without intermission, sleeping or waking, and seemed to grow stronger The arm began to feel tired and weak About the first of December the contractions would cease for a minute or two several times each day At this time she began to feel pain about the elbow and along the inner edge of the biceps extending as high as the top of the shoulder, and the muscle itself was tender to the slightest touch

March 3, she presented herself at my office for treatment At this time the contractions were more rapid but the movements of the hand were less extensive Intense pain was felt along the median and musculo spiral nerves, with considerable pain over the shoulder on both superficial and deep pressure The constant current of from six to eighteen cells was applied over the muscle and along the nerves for about fifteen minutes daily The current was alternated using first an ascending and then a descending current, but care was taken to avoid interrupting Under this treatment improvement was rapid, the spasm became less marked, finer, and the intervals of rest longer and more frequent The pain which I regard as due to a peripheral neuritis entirely subsided In May the contractions were reduced to mere tremor, not unlike that seen in paralysis agitans, but on closer examination it is seen to be due to the successive and rapid contractions of the pronator A tracing taken over the muscle at this time showed about 400 to 420 distinct contractions a minute



No 1



No 2

Read from left to right The upper line in each tracing records the number of contractions, while the lower one represents the rate at which the drum was revolving in seconds of time No 1 shows the contractions as nearly equal in number and extent, and is typical of the larger number taken No 2 illustrates the effect of slight involuntary inhibition of the muscle the wider excursions of the pen and the wavy outline of the whole tracing represent slight movements on the part of the patient

From this time improvement continued, the intervals of rest became longer and more frequent, and during sleep the spasm ceased At present the tremor is so slight as to scarcely attract the attention of the patient She says that it probably ceases much longer than she is conscious of, for her attention is not called to the hand for hours at a time

This condition has never been associated with any incoordination of the other muscles of the arm Writing was accomplished without much difficulty, but caused great fatigue owing to the effort of the other muscles to overcome the action of the pronator The longer strokes were often wavy not unlike the appearance in beginning sclerosis During the course of the difficulty no other symptoms of nervous disturbance were present though they were carefully looked for Sleep was good except during the early part of the trouble when the movements were considerable The general health was not impaired No internal medicine was given excepting full doses of arsenic for about three weeks, which did not seem to influence the course of the disease

DISCUSSION

DR FRANK WOODBURY, of Pennsylvania, had had a patient, a girl, who had a clonic muscular contraction for two months It may have been hysterical There may have been malnutrition and defective innervation in the case under consideration

DR H DUNCAN BULKLEY, of New York, asked how much arsenic Dr Moyer gave

DR MOYER said that he gave gtt iij three times a day, and increased to gtt ix at the end of a week He rarely gave arsenic oftener than thrice daily, and that after meals In the case reported he saw no symptoms of uræmic poisoning or of gastric disturbance He has seen a chorea confined to a group of muscles or to the hand, but such contraction as in the case mentioned was never seen in chorea The pathological changes in the case may have been in the muscles, but he did not think so Except in chorea, paralysis agitans and sclerosis the pathology of muscular spasm is not well understood

---

DIPHTHERIA AND TRACHEOTOMY

Read before the Medical Society of the District of Columbia, April 13, 1887

BY LACHLAN TYLER, M D,

OF WASHINGTON, D C

As common and fatal as this disease is, the profession is still more or less at variance regarding a discriminating definition of diphtheria In the opinion of many it is a malady separate and distinct from that other, so closely allied to it and termed pseudo-membranous croup, while on the part of others the belief is that the two diseases are really identical

It is partly with the hope of eliciting from the members of this society an expression of opinion concerning the questions of unity and duality that this brief communication is presented Only by free and full discussion, if necessary oft repeated, can a matter in such great dispute ever be brought to final settlement If there be but one disease—diphtheria —*that fact had better* be plainly and decisively con-

ceded, and the mind thenceforth disabused of any further idea to the contrary

It is not a difficult task to appreciate the harm which might be perpetrated by a confusion of ideas consequent upon a false conception of the illness to be treated Under such circumstances the sthenic condition attributed to so called membranous croup would be sufficient to restrain the hand in the beginning from administering appropriate remedies in anticipation of the treacherous onset of the asthenia of diphtheria, which, as subsequent events would show, had all along been in existence According to my own judgment, no distinction can be safely drawn in practice between the two diseases, and as a rule there is no good reason for making any Even in the minds of those who cling to the opposite belief a doubt is harbored, in the greater number of cases, as to which is presented, and the precaution is nearly always very wisely taken to provide against the possibility of its being diphtheria No comment is necessary upon making this simple statement

The effort to exact a pathology for each, which in essential particulars should possess a sufficient number of points of difference to distinguish them, has had no good results, and, indeed, can be said to have practically ended in failure The etiological factors, also, traceable in the history of the two affections, have not been shown to be dissimilar with any pronounced exactness

The greatest mistakes have ever and again occurred by relying upon the peculiarities of the membranous deposit for distinctive evidence of the existence of one or the other disease The simple truth would seem to be that it varies in character according to the severity and degree of penetration of the inflammatory process How far and in what manner this process is influenced by the constitutional state of the patient is not always clearly indicated The local effects are sometimes as severe in those with little bodily vigor as in the more robust, leaving whatever may be the amount of inflammation to be principally ascribed to the localization of the specific cause of the disease

In fatal cases of pseudo membranous croup it is maintained that death is primarily the result of asphyxia, due to membranous stenosis of the larynx, while in diphtheria the idea obtains that it is more in consequence of a septicæmia or toxæmia, ultimately producing paralysis of the vital forces

It is within the experience, however, of almost every practitioner to have seen cases of the former develop into well recognized diphtheria, and terminate accordingly, and of the latter disease, commencing in the most typical manner in the fauces, pass downwards and become complicated with croup On account of these facts it cannot but be admitted, therefore, that the two diseases are, at any rate, interchangable, and it would be going only a step further to believe that primary diphtheritic laryngitis might occur as well as diphtheritic faucitis or pharyngitis

If the two diseases are the same, the difference in contagiousness between them has been explained by their respective situations, and that in temperature in like manner In other words, if the larynx alone is attacked the infectious principle is situated at a safer distance than when located in the pharynx, and, according to observation, the temperature is likewise increased when the disease occurs at that point Glandular enlargements accompany membranous croup as well as diphtheria, and in each are dependent upon the degree of inflammatory action which may be going on They have been noticeably absent in some of the cases I have attended

The same sequelæ, including paralysis, are witnessed after either affection, the plain truth being that fewer cases of diphtheritic laryngitis survive, and they are, therefore, seen oftener when the diphtheritic process has remained confined to the pharynx

All pseudo membranous sore throats, occurring idiopathically, should for safety's sake, if for no other reason, be set down and treated as though they were diphtheria Those resulting from traumatic causes should of course have a different significance attached to them, and receive attention in accordance therewith

I consider it necessary to mention the name of only one man who may very properly be placed as authority at the head of those believing diphtheria and croup to be identical, viz Jacobi "In fact everything that has been written," says Dr Joseph E Winters, of New York, "by those who have contended that membranous croup is an independent disease, distinct from diphtheria, is nearly a compromise, and does not give one tenable diagnostic characteristic between them" To this I will add that there may be certain *library* differences between the two diseases, but none of clinical value

The question as to whether diphtheria is primarily a local or a constitutional disease still remains a mooted one That it is a local disease with a constitutional expression is, in my opinion, the correct conclusion, but the fact that it is opposed by many whose prominence in the profession entitles them to be heard with respect, and merits for their views the most deferential consideration, should prevent any one from assuming an attitude at all dogmatic in the premises Besides a considerable number of others, Oertel may be cited as advocating the theory that diphtheria commences in the throat, and that subsequently the whole system becomes infected by septic absorption through the lymphatic channels

All parties, however, occupy neutral ground in dealing practically with the subject, for from either standpoint, in order to gain any advantage over the disease, the treatment, so far at all generally approved, when carried out in full is always the same in principle and effect

In regard to treatment it is well to say that too much emphasis cannot be employed in condemning the idea that there is a specific remedy for diphtheria in the possession of anyone It is a threadbare argument that if such a remedy existed the great multitude advised and employed would not have been forthcoming, nor undergo such frequent additions In computing results from the various drugs administered for the cure of diphtheria nothing much more favorable to one than to another of them can

be discovered, and without being too sceptical, the belief might well be entertained that at times recovery from the disease was in the main dependent upon the mildness of its course and the persistency with which watchful care was observed

The statistics of Dr N Lunin, of St Petersburg, published in 1885 (*Medical Record*, vol 28, No 3), afford a fair idea of the utility of certain fashionable remedies Two hundred and ninety six cases were treated in the Children's Hospital of the Princess of Oldenburg All the children, with the exception of twenty five, are represented as having been well developed and well nourished The list of remedies used was composed of corrosive sublimate, iron, chinolin, resorcin, bromine and turpentine In the "phlegmonous septic" form of the disease, according to his classification, iron proved superior to any of the others, the deaths under its administration, however, reaching 76 5 per cent In the "fibrinous" form the oil of turpentine gave the best results, only 8 3 per cent of the cases treated with it dying

The treatment by iron and chlorate of potassium internally seems to have become the one quite generally agreed upon as being the most satisfactory The practice of administering iron, however, in such enormous doses to young children as ʒj, or more, frequently repeated, finds, and I think rightly so, little favor with the profession at large

The effort to use the spray too frequently and in spite of any violent resistance on the part of the child, is, in my judgment, an unjustifiable and hurtful procedure, in view of the additional amount of exhaustion it is likely to produce If its use, however, can be accomplished without unduly exciting the little patient to opposition, no question can be raised concerning the benefit it is capable of conferring

The insufflation of sulphur and other powders has at various times been highly recommended, but I have never witnessed any remarkably good results from it

Inunction with the oleate of mercury—a method of treatment, by the way, strongly advocated before this Society several years ago—has in my hands failed to produce the good which was to be expected

Remembering the asthenic tendency of the disease, it can only be in exceptional cases, and when our one desire is to lessen and render easier of expulsion a very thick and tenacious membrane, that such a depressant as pilocarpine can be given with any degree of safety or propriety Its use for eliminative purposes, in reference to the *materies morbi* of the disease, might far better be discontinued, as it is undoubtedly too dangerous a medicine with which to make such experimental tests It is safer to rely upon ipecac, zinc, turpeth mineral, or some other emetic whose effects, though practically the same so far as dislodging the membrane goes, are, comparatively speaking, less permanent in duration, and could, at any rate, more certainly be counteracted, should the occasion arise, by stimulants given with timely precaution

The carbonate of ammonium, given alone in full and frequent doses from the outset, and, if subsequently required, in conjunction with whisky, is a remedy in which, I am convinced, too much faith cannot be placed Not only as a diffusible stimulant is it exceedingly valuable, but as a solvent of the diphtheritic membrane also, in which capacity it possibly excels all others by the mode of its action through the circulation

Quinine deserves especial recommendation Given in tonic doses—preferably in the form of the oleate to the very young, by inunction—it seems to be potential in exercising a favorable influence in what might be termed its own peculiar way, and imparts to the physician a certain feeling of security and satisfaction difficult to define

Steaming, hot poultices, rubefacients—of which turpentine and camphor liniment are probably the best examples—and opiates to quiet restlessness and procure sleep whenever necessary, complete the catalogue of remedies of which I deem it worth while to speak

An ample supply of concentrated nourishment is always of prime importance, but here, at least, I do not believe in what is called forced alimentation Diphtheria becoming an acute wasting disease, must necessarily be accompanied by greater or less functional enfeeblement on the part of the digestive organs, which to be overtasked under such circumstances would only lead to complications of a character most certain to aggravate the preexisting low condition of the patient

Before leaving this part of the subject, I wish to say that any conflict of judgment arising between physicians in attendance upon any case of diphtheria —each with a hobby of his own concerning the most appropriate treatment to be adopted—is, in the present state of things, entirely uncalled for, since, as has been mentioned, there is no specific for the disease and, after all, there is very little difference in the results, it matters not what particular method of treatment is practiced The principal aim should be to prosecute any recognized mode of treatment which happens to be selected in a thorough and systematic manner, and without any vacillation, to the end

The operation of tracheotomy for the relief of the symptoms of diphtheritic laryngitis, while certainly not a difficult one to perform if ordinary care be exercised, remains in a more unsettled state than almost any other in surgery in reference to the exact time when it should be resorted to, and the extent to which benefit is conferred by it With the fact confronting us that many desperate cases recover under simple medicinal treatment, it cannot be successfully disputed that after the operation just as good grounds often exist for believing that recovery took place in spite of it, as that it was the means of saving the patient from what would have been otherwise inevitable death

The difficulty of deciding at the bedside upon the appropriate moment for the operation can only be overcome by authoritatively establishing it as the necessary practice immediately upon the occurrence of invasion of the larynx by the local process, as shown by the altered tones of the voice, and by the slightest interference with respiration

Ranke, of Munich, in a paper read at the fifty-eighth Congress of German Naturalists and Physicians, Strasburg, September, 1885 (*Medical Record*, vol xxviii, No 25), reported that upon the appearance of these symptoms he had operated the preceding seven and one half years in 45 cases with 19 fatal results, the number of recoveries therefore amounting to 57 8 per cent This is a higher percentage than is ordinarily attained when the operation is performed at irregular times, or principally for the relief of the most urgent symptoms of suffocation, and may be accepted as fairly illustrating all the advantages to be gained at the present time from the plan of operating so early

Were it not for the constitutional state engendered by the disease, the death rate from it would no doubt be reduced to the smallest proportions by the opportune performance of tracheotomy But even as it is, with the organism thoroughly impregnated with the poison of the disease, and in consequence engaging to a large extent in the production of the dyspnœa, it is nevertheless oftentimes instrumental in relieving so much of it as may be dependent upon the local causes which more directly tend to precipitate a fatal issue

A concensus of opinion is being very generally formed in favor of what may be called the *precautionary* performance of tracheotomy But in any instance in which, for good and substantial reasons, the operation is delayed, it should not follow that it must be entirely disapproved of, even as a *dernier ressort* The fact is, it may be appropriate at any period of the disease, but more particular when the *first* evidence of laryngeal distress is recognized It does not appear to be the only, nor, it might be said, been the principal effect of the operation, to admit of a supply of oxygen to the blood, because, in satisfying any demand for that elementary principle by other than surgical means, similar good results do not so positively occur I have had practical experience of this Aside from anything else, it no doubt also affords relief from certain nervous impressions causing many of the distressing phases of instinctive action

Without having had any experience with either intubation or deep tubing of the larynx, a substitute recently offered for it, I am inclined to think, after perusing the literature bearing thereupon, that as compared with tracheotomy they offer a more scientific and rational method of dealing with the majority of cases of diphtheritic laryngeal stenosis The double advantage they possess of being most effective in the later stages of the disease, and of presenting no obstacle to the performance of tracheotomy at any time, not to speak of the fact that they are calculated oftentimes to obviate the painful necessity of shocking the feelings of family and friends, or to at least establish euthanasia, would appear to be sufficient to commend them above and beyond tracheotomy in almost every instance How far they may hereafter succeed in revolutionizing that part of the treatment of diphtheria to which they are adapted cannot be foretold

The main objection offered to them, of disturbing the invalid to an unreasonable degree, and especially of subjecting him to the dangers of the upright position during the time occupied in introducing the tube, are not, I think, comparable in seriousness to those which can be advanced in respect to the measures resorted to in performing the operation of tracheotomy

MEDICAL PROGRESS.

MODIFIED LARYNGECTOMY —DR J SOLIS COHEN describes the following operation

1 Make an incision in the hyoid bone to the lower border of the cricoid cartilage, and exactly in the middle line

2 Carefully separate the sterno hyoid muscles

3 Hold the soft parts aside and insert, from above, one blade of a strong cutting forceps with narrow blades beneath one wing of the thyroid cartilage, one-fourth of an inch from the angle of junction with its fellow, and sever the cartilage vertically its entire length through to the crico thyroid membrane

4 Make a similar cut on the opposite side

5 Seize the freed angular portion of the thyroid cartilage, comprising its entire respiratory contingent, with a volsellum forceps, and draw it to either side, the soft parts being separated meanwhile from the inner surface of the detached wings of the thyroid cartilages with the handle of the scalpel

6 Make a transverse cut to sever the cricoid cartilage from the trachea (At this step, in the living subject, a sterilized cotton plug should be inserted into the upper end of the trachea, preliminary tracheotomy having been performed previously) (If the cricoid cartilage is to be retained, disarticulate the arytenoids, and then sever the soft parts above the cricoid instead of below This modifies the next step in the procedure accordingly)

7 Lift the cricoid cartilage forward and carefully separate it with the edge of the knife from the inferior edge of the cornua, laterally and superiorly, and then from the œsophagus posteriorly

8 Insert a finger into the pharynx from below and carry its tip over the epiglottis to draw that structure down

9 Divide the thyrohyoid membrane and the fibrous tissue still holding

10 Lift out the exsected respiratory portion of the larynx

The arteries likely to require ligation will comprise small branches of the superior, middle, and inferior laryngeals

Upon the living subject the operation should be strictly aseptic, and where practicable should have been preceded by several days by a preliminary tracheotomy The trachea may be occluded superiorly by a small rubber bag attached to the smallest sized soft catheter, introduced through the tracheal wound, above the canula, and then inflated The canula may be temporarily removed during the introduction of the bag and its inflation

Advantages alleged for this procedure

1 Its rapidity, ease, and comparative safety to the patient

2 The small size of the wound

3 The preservation of the attachments of the thyrohyoid ligament and of the greater part of the membrane, and of the thyrohyoid, sternohyoid, stylopharyngeus, and inferior constrictor muscles, leaving—

4 Important functional structures retained in their normal relations for deglution, and leaving—

5 A firm, natural support for the adjustment of artificial substitutes for the larynx

For these reasons it is submitted that this procedure should be preferred to complete laryngectomy whenever not precluded by extent of disease — *N Y Medical Journal*, June 18, 1887

CONVALLARIN AND CONVALLAMARIN —DR J N NATHANSON has made a theoretical and practical inquiry into the action of these glucosides Having reviewed the literature of the may-lily, he found that, as far as four chief preparations were concerned (viz, the infusion of the flowers, aqueous extract of the whole plant, tincture of the flowers, and American fluid extract), the opinions of various authors were by no means so contradictory and so doubtful as Langgaard had thought But—curiously enough—it proved otherwise in regard to the may lily glucosides, the active principles of the plant, convallarin and convallamarin (discovered by Walz in 1858), Marmé, who had experimented on both of them in 1867, found that convallarin was endowed solely with a purgative action, while convallamarin acted mainly on the cardiac muscle, being a "cardiac poison" Dr Isaïeff (1881) confirmed Marmé's statement on the latter substance, without touching the former But Dr Leubuscher (who apparently had worked with Tromsdorf's preparation) flatly denied any action of convallamarin, while Professor Maragliano and, later, Dr Bochefontaine declared that both of the may-lily glucosides possessed an identical action on the heart, the only difference being that convallamarin *acts stronger* than convallarin The first step made by Dr Nathanson, in view of this rather remarkable conflict in the statements concerning the "chemically pure active principles" of the plant, was to have the commercial glucosides analysed, a second, to undertake a series of therapeutic experiments at Professor Koshlakoff's clinic The first preparation of convallamarin obtained by him from Merck (in 1885) proved to be a mixture of that glucoside with convallarin and some products of decomposition of both, as an analysis by Professor A A Loesch had established The explanation of discrepancies between different observers was then pretty near Of course, no experiments were made with that preparation, and the purest glucosides were obtained from Merck to be given in four cases of disturbed compensation (in a patient, aged 15, with aortic regurgitation and relative mitral insufficiency, in two patients, aged 57 and 40, with aortic regurgitation alone, and in a patient, aged 48, with mitral regurgitation and stenosis) The results were these

1 Convallarin (given in the dose of from 0 06 to 0 12, three or four times daily for three to eight successive days) produced only nausea, diarrhœa, and gastric pain The pulse, breathing, daily amount of urine and dropsy either remained unchanged or showed unfavorable alterations

2 Convallamarin was administered in the daily (gradually increasing) dose varying from 0 03 to 0 3 gramme for eleven to seventeen successive days In one of the patients, to whom digitalis, scilla, caffeine, and adonis had been previously given and failed, convallamarin also remained, on the whole, inactive, the improvement consisting only in a slight decrease of dyspnœa and palpitation after exercise But in the remaining three patients a rapid and striking improvement ensued, the pulse became slower and more regular, the amount of urine augmented, dropsy decreased and all other signs of disturbed cardiac compensation gradually and steadily disappeared

3 Of accessory effects, only slight nausea, salivation, and giddiness were observed in one of the patients when the daily dose had been increased to 3 decigrammes, in another, slight nausea and vomiting made their appearance, when the daily dose had been raised to 0 35 and 0 4 gramme

4 *No cumulative action was ever observed* The general conclusion of Dr Nathanson is to the effect that convallarin possesses but a purgative action, while convallamarin represents a useful cardiac drug endowed with the power of re-establishing disturbed compensation, and free of any unpleasant accessory effects Selection of an absolutely pure preparation is a matter of paramount importance —*The London Medical Record*, July 15, 1887

METHYLAL —Methylal is a fluid of specific gravity 0 855, its vapor density is 38°, taking hydrogen as a unit, and a boiling-point of 42° Cent, 107 6° Fahr Its solubility in blood is one part in three, its composition is $C_3H_8O_2$ It is made by distilling methylic alcohol with sulphuric acid in the presence of peroxide of manganese, but it requires several redistillations before it can be obtained in the pure state, for which reason it is at present a very expensive compound When methylal is quite pure it is almost tasteless, but bites the tongue, and, owing to its low boiling-point, quickly evaporates The odor of it is fragrant, and not very powerful The pure vapor creates no irritation on being breathed After long exposure to the vapor of methylal, in an atmosphere containing not less than thirty-five per cent of the vapor, warm blooded animals may be made to pass into a sleep which, once established, is deep and prolonged

Methylal was first introduced by Dr B W Richardson, who in his early researches supposed that he had found that it was a marked narcotic, but he now states that he believes that the narcotism so produced was due to the presence of acetone from the methylal not having been sufficiently pure Recently, with a perfectly pure specimen, he endeavored to anæsthetize two dogs with methylal in order to enable them to be operated on painlessly After half an hour's inhalation of the vapor narcotism was not produced The fluid was then injected hypo-

dermically in one animal and to the extent of an ounce dose, upon which a gentle sleep, or rather intoxication, followed, but with no sufficient anæsthesia to allow painless operating In action as a medicine, methylal lies between alcohol and anhydrous ether It quickens the action of the heart with reduction of arterial pressure, it makes the respirations slow and deep, it induces a tendency to sleep, and it is a sedative to pain, but not to a very deep degree On the whole, it would be best to keep it in the group of anodyne antispasmodics, in which Dr Richardson originally put it It causes very little muscular excitement and no vomiting, but after long inhalation of its vapor it produces a free flow of saliva As it mixes well with alcohol and with ether it might be administered with either of these agents, and it might also be given with amyl nitrite for the relief of colic, asthma, angina pectoris, or tetanus, but before it can come into general use it must be reduced in price

Methylal is very soluble in water, and may be administered by the mouth when diluted with water, or by hypodermic injection Dr Richardson recommends commencing with a dose of a fluid drachm, mixed either with glycerin or syrup of orange flowers and distilled water —*Therapeutic Gaz*, April 15, 1887

ANTIFEBRIN AS AN ANODYNE IN SPINAL SYPHILIS —DR HENRY M FISHER reports (*Medical News*, July 23, 1887) a case of spinal syphilis in which severe pains yielded to five grain doses of antifebrin "The pains were due, I believe, to gummatous infiltration of the posterior columns of the spinal cord The patient contracted syphilis twenty-two years ago, and when I first saw him, ten years after the primary lesion, he complained of severe intercostal pains, so, even at that time, it is probable that there had been some infiltration of the spinal cord A few months later *right* optic atrophy occurred, and hearing in the *left* ear became much impaired At about this time paralysis of the facial muscles and hemianæsthesia of the tongue occurred In 1880 he had a fall on his head, and, a little while later, was found to be suffering with mental aberration and was treated for some months at the Insane Department of the Philadelphia Hospital, and later, at the Norristown Asylum In 1881 there was marked paresis of the left leg, and severe intercostal and girdle pains were complained of Under specific treatment, the pains diminished in severity, but, since another attack of the left hemiplegia last autumn, they seem to have occurred more frequently and with greater severity They were described as sharp, cutting pains, and extended from the upper intercostal spaces to the sacrum and also along the course of both sciatic nerves, more particularly the left There has been, at no time, any paralysis of the bladder

On June 22, having administered several quarter-grain doses of morphia with the effect of giving him only temporary relief, I ordered him an antifebrin (grs v) to be taken whenever pains were particularly severe One week later patient stated that he had not felt so well for a year The first powder checked the pain in less than half an hour When the pains recurred they seem to have been less violent, and, each time, five grains of antifebrin sufficed to check them, and so, after five days of this treatment, and after taking forty or fifty grains of antifebrin, patient is, temporarily at least, entirely free from pain"

July 8 Patient has had slight recurrence of the pains during the past week, but they were apparently far less severe than they were before No sweating and no prostration were caused by these doses

ALCOHOLIC CIRRHOSIS OF THE LIVER —MM STRAUSS and BLOCQ have made numerous experiments in regard to this matter They injected directly into the stomachs of rabbits daily a dose of 15 grams of a mixture of absolute alcohol, methylic alcohol and 1 part of water The animals usually fell at once as though by a stroke of lightning, and remained in deep coma for several hours When the animals were killed after a certain time the liver was found to present to the naked eye no very marked changes, and the surface was smooth, but the cut surface showed the acini apparently surrounded by a grayish-red zone or line In the livers of rabbits intoxicated for four or five months the ultimate peri lobular portal channels appear infiltrated with embryonic cells When intoxication is maintained for six or eight months the lobules are surrounded by a ring of embryonic cells There is thus produced a monolobular cirrhosis which realizes almost perfectly the scheme of Charcot Nothing is more natural than this localization of the lesion Alcohol reaches the liver through the portal vein, and one would naturally suppose that it would affect at first that part of the organ with which it comes in most perfect contact —*Semaine Medicale*, July 20, 1887

ANTIPYRIN IN UTERINE COLIC —M CHOUPPE reported to the Société de Biologie his successful treatment of two cases of uterine colic with antipyrin injections The first was in the case of a woman who suffered at each menstrual period with very painful colic which was with difficulty overcome by opium and chloral Antipyrin in the dose of 1 gram gave rapid relief The second was the case of a woman suffering from uterine colic following childbirth The pains were lessened for five hours by a first injection, and disappeared completely under the influence of a second —*Semaine Médicale*, July 20, 1887

NEW SUBSTANCE IN TUBERCULAR TISSUE AND ORGANS —E FREUND has found in various organs, as well as in the blood of tubercular patients, and both in the tubercle granules and in the diffuse tubercle tissue, a substance which he regards as cellulose because of its elementary analysis and its reactions He looks upon it as an essential part of the tubercular growth and of the blood of tubercular individuals This substance was not found in tissues and blood affected by various other diseases —*Centralbl fur klin Med*, No 27, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

DIET IN ALBUMINURIA

First in importance in the hygienic treatment of albuminuria, says Dr Purdy, in his excellent work on Bright's disease, may be ranked the diet of the albuminuric patient It is a subject to which very much study has been given, and which requires very much more In some observations recently made DR T GRAINGER STEWART, of Edinburgh, has sought to throw additional light on the question of the possibility of producing albuminuria by diet in persons whose kidneys were healthy, and to the effect of various forms of diet in patients affected with albuminuria

That slight, and sometimes marked albuminuria appears after meals is a well known fact, the mere ingestion of food of any kind will produce albuminuria in some persons, while others are only affected by particular articles of food The experiments of Stokvis, Lehmann, Lauder Brunton, Power, Dobradin, Claude Bernard and others in regard to the causation of albuminuria by egg-albumin, are so well known as not to require more than mention here In order to gain further information on this question Dr Stewart selected four persons whose urine showed no albumin even when tested with picric acid, and whose condition offered no objection to such a test

The first patient, one with locomotor ataxia, took ten raw eggs daily, in addition to his ordinary diet, for nine days Albumin appeared in two days from the beginning of the experiment, and while not large was sufficient to be shown by picric acid Twice it was shown by nitric acid, and each time an excess of the acid dissolved the coagulum, showing that it was not egg albumin but blood albumin that was present The albumin persisted from the day on which it appeared, but disappeared on the day on which the eggs were stopped In the second case, one of mitral incompetence, nine eggs were given for seven days "Albumin appeared on the first day, persisted throughout the experiment, and disappeared when the eggs were discontinued " It was distinct with picric acid, but was never shown by nitric acid The third case, a person free from organic lesion, was given ten eggs daily for three days in addition to his ordinary diet Albumin was distinct with picric acid on the first and third days, on the second it was sufficient to show with nitric acid, and the opacity disappeared when an excess of acid was added The fourth case, one of chorea, did not bear the eggs well, only three were given, and for three days only In this case also albumin was shown by picric acid while the experiment continued These experiments show "that the introduction of raw egg-albumin into the stomach causes albuminuria, that the albumin is always in small quantity, that it disappears when the ordinary diet is resumed, and that it is not egg-albumin, but serum-albumin which is discharged " This kind of albuminuria, therefore, cannot be explained on the theory of the absorption of egg-albumin as such into the blood, and its discharge from the kidneys, and the experiments further explode the speculation, in regard to this question, of the minute size of the molecules of egg-albumin and its greater transfusibility

By way of explanation Dr Stewart offers two suggestions First, owing to the large amount of albumin digested and absorbed the blood becomes surcharged with this material, and some of the excess escapes by the kidneys The second suggestion is related to some recent investigations made by Ralfe, Noel-Paton and Oliver Ralfe has shown the relation of functional albuminuria and hæmoglobinuria to the rate of destruction of the red corpuscles, and the formation of urea Noel-Paton has shown some of the relations existing between bile secretion and the formation of urea Oliver has shown that urea is mainly formed from the red corpuscles, and that the most active period of urea formation is when the liver is actively secreting during digestion In the light of these observations, then, it is reasonable to suppose "that in our experiments the liver was stimulated to excessive activity owing to the excessive amount of proteids ingested, that thus the red corpuscles were more rapidly destroyed, and that the albumin liberated from them not being all transformed into urea, was in part discharged by the kidneys " This suggestion is partly confirmed by the

facts observed in the test cases as to the urea discharge In the first three cases the urea was over normal while the eggs were taken, and fell back when the eggs were discontinued

From some experiments made on boys with cheese and walnuts Dr Stewart draws the general conclusion in regard to the effect of diet on the production of albuminuria in healthy persons, that while the ingestion of food has been shown frequently to produce albuminuria from idiosyncratic peculiarities, particular articles of diet induce it in some people, and while we may succeed in inducing it by the use of special articles of diet, yet the quantity of albumin is usually minute, and it has little tendency to persist after the return to ordinary food

---

In regard to the question of diet in Bright's disease, Dr Stewart made some experiments with five diets ordinary, large, milk, low, low diet with eggs It may be said that the compositions and weights of these forms of diet are as follows ordinary diet, 59 ounces, 15 24 parts of carbonaceous and 4 25 nitrogenous matter, large diet, 71 ounces, 19 10 parts carbonaceous and 5 68 nitrogenous, milk 60 ounces, carbonaceous 6 4, nitrogenous 3 6, low diet, 65 ounces, carbonaceous 18 98 parts, nitrogenous 2 94, low diet with eggs, 8 raw eggs 14 5 ounces, carbonaceous 4 35, nitrogenous 5 8, and otherwise as in low diet The points determined in each case were the weight of the patient, daily quantity of urine, its specific gravity, the amount of urea, and the amount of albumin in grams per litre, determined by Esbach's method

In three cases of inflammatory Bright's disease the experiments, while not sufficient to warrant general conclusions, supported the view that milk diet or low diet are better suited to such cases than ordinary or ample diet In a case of cirrhotic Bright's, with inflammatory superadded, the ordinary and milk diets were used for periods of six days each, but without showing any effect upon the amount of urine or urea, and the albuminuria was not diminished by the milk diet From experiments on several cases of pure cirrhosis of the kidneys Dr Stewart is inclined to think that in this form of Bright's disease the diet is a less important element than it is in the tubular inflammation He has had no opportunity of making an extensive series of experiments on cases of waxy or amyloid kidney, but so far as his evidence goes he is inclined to think that the good nourishment which is otherwise indicated in that disease is not contra-indicated by the state of the kidneys, even though their vessels appear to be in a condition permitting of more ready transudation of albumin than is the case with healthy vessels

---

The diet in the forms of albuminuria not dangerous to life may be given a short consideration In cases of febrile albuminuria, says Dr Stewart, the question of diet is usually of little moment, but in some, and especially in scarlet fever, there is a special liability to the occurrence of renal inflammation, and there is no doubt that a copious diet rich in nitrogen is very dangerous, and that something of the nature of low or milk diet is best for such fever cases, in convalescence as well as during the fever In the dietetic and persistent varieties of functional albuminuria individual peculiarities as to food are to be studied In accidental albuminuria diet is often of great importance "Above all, in cases of catarrhal inflammation of the urinary tract bland and milky diet is to be recommended I have often seen," says Dr Stewart, "great advantage in such cases from the adoption of an exclusively milk diet" But in some of the cases of albuminuria ordinary diet is best Alcohol is to be avoided in all cases of Bright's disease and in cases of inflammatory accidental albuminuria, unless there be need of direct stimulation of the circulatory or nervous systems

---

UNSATISFACTORY MEDICAL APPOINTMENTS

Under this caption in THE JOURNAL of July 30th, 1887, we copied a preamble and resolution from the reported proceedings of the State Medical Society of W Va, disapproving the action of the Governor of that State in appointing Dr Geo I Garrison, of Wheeling, to fill a vacancy in the State Board of Health, on the claim that such appointment was in violation of "the letter and spirit" of the law defining the qualifications required for eligibility for membership in such Board We have received from Dr Garrison a copy of the Wheeling *Daily Register*, of August 18th, 1887, containing the Governor's reply to the charges made against him, from which we copy all that relates directly to the question of violation of the law in appointing Dr Garrison as a member of the State Board of Health It is as follows

"What the objections are to Dr Garrison's appointment the resolutions do not disclose, but I have ascertained from members of the Society that they are,

"First—That he had not practiced medicine the required time—twelve years—before his appointment

"Second—That he received his diploma from a medical college after one course of lectures, instead of two

"Until 1881 there was no law in this State regulating the practice of medicine, and neither examination nor diploma was required of the practitioner

"The following is the law applicable to this case

"'1 There shall be a State Board of Health in this State, consisting of two physicians residing in each Congressional district thereof, who shall be graduates of reputable medical colleges, and who shall have practiced medicine for not less than twelve years continuously They shall be appointed by the Governor, and hold their offices for the term of four years, unless sooner removed as provided in this chapter But the members of said Board now in office shall, unless removed therefrom, remain in office until their successors are appointed and qualified'

"From the evidence before me, and of which I have no doubt, Dr Garrison had been practicing medicine for six years before the passage of the Act of 1881, but was not at that time a graduate of any medical college

"In June, 1881, he appeared before the State Board of Health, was duly examined, and thereupon a certificate was issued in due form authorizing him to practice medicine

'Dr Garrison attended the Fall and Winter Course of Jefferson Medical College, 1885-6, was admitted into the senior class and was graduated as Doctor, in April, 1886"

The exact facts, then, as presented by the Governor himself are, that Dr Garrison had practiced medicine in the State of West Virginia, six years prior to June, 1881, but without having attended or graduated in any medical college In June, 1881, he was examined and licensed to practice medicine by the State Board of Health In 1885-6, he attends one course of lectures at a medical college, and graduates at the close of the session, in April, 1886 In 1887 he is appointed by the Governor a member of the State Board of Health Therefore, according to Governor Wilson, six years' practice without either license or diploma, five years with a license from the State Board, and *one* year with a diploma from a medical college, is equivalent to being "a graduate of a reputable medical college, and in the practice of medicine for not less than twelve years continuously" It is not surprising that the members of the State Medical Society should differ from the Governor in this interpretation of the law We claim to know nothing concerning the qualifications of Dr Garrison, any more than we do concerning those of Dr H V Ferrell, of Williamson Co, who was recently appointed by Governor Oglesby a member of the Illinois State Board of Health

THE INTERNATIONAL CONGRESS —Before another number of THE JOURNAL reaches all of its readers, the Ninth International Medical Congress, of Washington, will have completed its sessions, and its work have passed to the hands of the historian It is not for us to predict what the character of the work will be, but we have the satisfaction of knowing that, through the faithful work of the Executive Committee and the untiring zeal of the Local Committee of Arrangements at Washington, every preparation has been made for the accommodation and entertainment of an International gathering of medical men equal in numbers and in scientific and professional achievements, to any that have preceded it

ALL THE CONDUCTORS on the Maine Central Railway have been provided by the management of the road with cases containing all the remedies to be used in cases of accident, such as linen and rubber bandages, plaster, surgical instruments, medicines, liniments, etc, with books of directions Every conductor will be his own doctor The occasions are frequent also in times of accident when physicians are passengers upon trains, but they are often handicapped by lack of proper instruments A further step in the right direction would be to have all trainhands and employes instructed in "aid to the injured"

ASSOCIATION OF AMERICAN MEDICAL EDITORS —The officers of this Association, in accordance with a resolution adopted at the last annual meeting, have completed the arrangements and will give an elegant Banquet to the medical editors from other countries, on Monday evening, September 5, at the Riggs House, Washington, D C That it may not conflict with the general Conversazione of the Congress in the U S Pension Hall the same evening, the Banquet will begin at 10 P M

AMERICAN ACADEMY OF MEDICINE —The next Annual Meeting of this Society will be held in Columbian College, Washington, D C, on Saturday, September 3d, at 12 o'clock, M A collation will be served in the evening of the same day at the Arlington House The meeting, though short, will doubtless be one of interest and enjoyment

NATIONAL CONFERENCE OF STATE BOARDS OF HEALTH —The fourth annual meeting of the National Conference will be held at Willard's Hotel, Washington, D C, Wednesday and Thursday, September 7 and 8, 1887, commencing at 10 o'clock A.M

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, April 13, 1887

THE PRESIDENT, JOS TABLER JOHNSON, M D, IN THE CHAIR

DR LACHLAN TYLER read a paper on

DIPHTHERIA AND TRACHEOTOMY

(See page 269)

DR S C BUSEY said that in view of the recent discussion on this subject before the New York Academy of Medicine, he had no desire to open the debate He had nothing new to offer and could only give expression to his opinions and experience Some years ago, when the subject was very elaborately discussed before this Society, he stood almost alone in advocacy of the doctrine of the unity of diphtheria and croup Now, he believed, the doctrine of unity was generally accepted Not only did he accept the doctrine of unity, but he believed that croup, diphtheria and inflammation of the tonsils and pharynx were interchangeable affections This view had been taught by Trousseau, Brettonneau and others, and he thought he had frequently witnessed illustrations of it both in private and hospital practice Recently in one family five cases had occurred The first was a case of pharyngitis in which there was no membraneous formation, nor any local evidence of a diphtheritic character The child was—according to his uniform custom in all such cases—isolated, only the mother and adult sister, who nursed the patient, being permitted to enter the room A few days after the recovery of this child, another child, who had been allowed to remain in the room previous to his first visit, was seized with diphtheria, perfectly marked from the beginning This child died, and subsequently the mother and sister, who had nursed both children, were taken with diphtheria A nursing baby remained with the mother during the first night of her sickness and also had the disease Some years ago, during his service at the Children's Hospital, diphtheria, croup of the larynx and simple sore throats appeared in the same ward, during the same period of time, in a manner which had convinced him of their interchangeability

Diphtheria is not a disease peculiar to large cities, or to dense populations, but prevails with equal, if not greater virulence and mortality in villages and sparsely populated regions It is most prevalent in those regions of country, and in those localities where anginas are most frequent, and at that season of the year when the climatic and atmospheric conditions are most favorable for the production of sore throats, and among those most exposed to such causal influences These considerations favor the view of their interchangeability He believes diphtheria to be primarily a local disease, and that systemic infection, sooner or later, and to a greater or less degree, took place Hence he believed that any sore throat, under favoring conditions, might become diphtheritic For this reason he always isolated cases of sore throat

Clinically, he divides diphtheria into three forms The first is so mild that the constitutional symptoms are very slight or absent The fever is usually very slight and the membraneous formation is generally limited to the tonsils The intensity of the fever is not, however, diagnostic of diphtheria for it is frequently very high in cases of simple sore throat The second form is characterized by marked local symptoms and grave constitutional conditions This is the most prevalent form, and many cases proved fatal The third form comprised those cases in which the patient seemed from the beginning to be overwhelmed with a septic and potential poison, and death is inevitable Such cases seemed to be constitutional from the beginning, and could not be explained upon the theory of local origin

Diphtheria is both contagious and infectious Its contagiousness is limited to the direct contact of the poison with an irritated or inflamed surface, and its infectiousness is certainly less than that of the exanthemata The former property is proven by the well-known fact that physicians in attendance have contracted the disease by the contact of the poison on inflamed surfaces, and the latter is shown by the escape of other members of a household in which there is a case of diphtheria He has probably seen fewer cases of diphtheria than other physicians of equal opportunities This he attributes to the fact that he always isolates cases of sore throat in children, and has always taught his clientèle the importance of prompt and proper attention to the simplest angina He regards all cases of diphtheria, however mild in the beginning, as dangerous, hence at the onset he begins with a vigorous local and constitutional treatment

Diphtheria is characterized by inflammation, the production and absorption of a poison, a membraneous exudation, and the emanation of a poison Except, perhaps in one form, the constitutional symptoms of systemic infection follow the absorption of the poison generated during the progress of the disease

His treatment is both local and constitutional He avoids all injury to the inflamed parts In fact he does not favor the rapid dissolution of the membrane unless it interferes either with deglutition or respiration, but prefers gradual dislodgement of the membrane by warm fomentations or poultices, externally, and warm, alternating with cold antiseptic spray As an antiseptic he prefers carbolic acid Has not used the bichloride of mercury solution He has had no experience with trypsin, but has frequently succeeded in dissolving the membrane with a solution of lactic acid, employed either as a lotion or a spray After dissolving the membrane he had brushed the inflamed surface with the oleate of mercury and at one time believes it prevented the re-formation, but has abandoned the practice because additional experience had satisfied him of its uselessness When the membrane is removed by solution it usually reforms, but when slowly detached by the method stated it does not often reappear Of the constitutional remedies he considers the tincture of the

chloride of iron, a nutritious and sufficient dietary, alcoholic stimulants when needed, quinine in tonic doses, and the chlorate of potassium, in moderate quantity, as the most important The iron is both tonic and antiseptic, the quinine is tonic and antipyretic The chlorate of potassium is dangerous when employed, internally, in large quantities He has no doubt that it may produce nephritis For spraying he employs a carbolized saturated solution of chlorate of potassium He has employed the bichloride of mercury internally, but has lost every patient to whom it was given Many children are lost because of the failure of the nurse to execute the orders of the attending physicians, and by the opposition of the parents If every child suffering from diphtheria could be taken to a hospital and isolated from its parents he thinks many cases would be saved that are now lost

Tracheotomy in cases of diphtheritic croup very often fails because the operation is performed too late Intubation gives promise of greater success

It is not a cutting operation, and even if it does not bring relief it does not preclude the possibility of tracheotomy It can be done early without fear of harm, and it does not necessarily require an expert to perform it Dr Montgomery reports 13 cases of intubation with six successes, a better proportion than tracheotomy would probably give The tube should be small and not fill the lumen of the larynx so that the membrane may be coughed up alongside the tube

To determine the time for operation is most difficult The opinion is now, as it always has been, that the early operation is the most successful, but it is almost impossible to determine the time at which it is an operation of expediency Later it becomes an operation of necessity Perhaps if the rule was to perform tracheotomy immediately on making the diagnosis more cases would be saved In his opinion the operation is indicated as soon as our best efforts fail to remove the membrane This practice cannot, however, be carried out in private practice, because an operation which will not guarantee a success is resisted by the parents until it is too late Recession of the chest wall during inspiration is the usual indication for tracheotomy, but in his opinion that is at too late a period The presence, however, of a false membrane in the larnyx is not always the indication for tracheotomy He recalls an instance where he was called to the Children's Hospital to see a case of diphtheria When he arrived he found the surgeon just about to perform tracheotomy He declined to permit it, but gave an emetic of turpeth mineral The membrane was detached, and the child got well

Dr Swan M Burnett thought that it was well to have the opinion of all the departments of medicine upon the subject, and for the ophthalmologists he would speak It is well known that we have a diphtheritic conjunctivis as well as diphtheria of the larynx High authorities in modern ophthalmology have been able to differentiate a croupous from the diphtheritic form of conjunctivitis, and as we have the eye under observation from the beginning to the end of the trouble this duality cannot be disputed The diphtheritic membrane is part and parcel of the conjunctiva itself, and cannot be wiped away In what we call the croupous form the membrane is on the surface and can be easily wiped away leaving a bleeding surface In diphtheria the lids are hard and swollen, red and shiny These conditions are not present in as great a degree in the croupous form The treatment of both is nearly the same although the croupous form is easier to cure Antiseptics play an important part in this At one time a strong solution of nitrate of silver was used in Germany, but the treatment is not now so heroic Luckily the diphtheritic form is rare in this country, and he has himself never seen a case of it

Dr Busey said that what Dr Burnett called croupous membrane was not diphtheritic but a simple exudation

Dr Burnett replied that it is only in recent years and after the most careful research that the difference between the two membranes was discovered, and their characteristics well proved

Dr J W H Lovejoy believed with Dr Busey that diphtheria was at the beginning a local disease, which in a short time becomes constitutional, and should be treated as such A few months ago he attended a child with a diphtheritic membrane over the soft palate and naso pharnyx He gave at once iron and chlorate of potash both internally and as a gargle, and in addition lime water applications both day and night The membrane, however, increased, and he resolved to try trypsin He dissolved 30 grains of trypsin and 15 grains of bicarbonate of soda in an ounce of water, and ordered the throat to be sprayed with that every hour, meanwhile keeping up the other treatment After a day's use of this spray he was astounded to find that nearly the whole of the membrane had disappeared He considers the happy termination of the case was due to the fact that the trypsin dissolved the membrane and thus allowed the gargle to reach the throat He thinks that an inflamed throat forms a suitable midus for diphtheritic infection Ten years ago he was attending a case of diphtheria, and upon going out of the house in a heated condition he took cold In two days he discovered a diphtheritic patch upon his tonsil, and he was quite sick with the disease He has not for many years used irritating substances to the throat, but has relied chiefly upon iron and chlorate of potash He is also opposed to any surgical interference In a case in which there was a copious deposit of membrane and great difficulty in swallowing, he was advised by a consulting physician to remove a small portion of the uvula which was much swollen This he did, but in a few hours the membrane was over the raw surface and the child died From this, and the reports of other successful cases from the use of trypsin, he would recommend that article for a fair trial

Dr M Murray said that diphtheria was certainly a local disease at first He has seen Storck on three occasions remove a diphtheritic membrane with a brush, and paint the denuded surface with a solution of bichloride of mercury, and the membrane had never returned

DR L TYLER did not believe that the lack of oxygen was the principal indication for tracheotomy, as we can supply that by giving inhalations of it The effect is not, however, the same as from tracheotomy Those cases in which it is difficult to decide whether the disease is local or general are the exceptions which "prove the rule" of its local origin He prefers to use quinia in small tonic doses, to large antipyretic doses As antipyretics he would prefer to use either cold or antipyrin, the latter only when there is no great depression of the vital forces He uses in his paper the term "precautionary tracheotomy" by which he means an early operation, and so far as he knows the expression is original

He considers tracheotomy one of the easiest operations in surgery, but the trouble is we delay it until it is often too late Thus a dread of the operation has been engendered among the profession and the laity from the number of fatal cases, which are due to the disease and not to the operation Tracheotomy of itself is not a dangerous operation as it does not kill when done for other reasons than for diphtheritic stenosis In on operation which he did the child was already *in extremis* He etherized and opened the trachea, and the patient was somewhat relieved, but it died on the table Another case he saw in the morning and was convinced that tracheotomy was needed, but he had not the courage of his convictions, so he put it off a few hours until he could obtain a consultation At the end of that time the membrane had spread so extensively and the constitutional infection had become so profound that an operation would have been useless and was therefore not performed

DR J FORD THOMPSON said that he was surprised to hear Dr Tyler call tracheotomy an easy operation For his part he had studied the subject carefully and has done many operations, yet he feels as much trepidation on beginning the procedure to-day as he did at first He does not think that tracheotomy for diphtheria is comparable with tracheotomy for any other condition, nor is the operation as difficult on adults as on children There is scarcely a fatal case of which it is not said that the operation was done too late It is his custom never to operate on a case that can be saved by other means, and in one winter he saved four children that were almost moribund when he began the operation It is said that the early operation saved more children than the late This may be so, for it is probable that many cases would have recovered without the operation He has had but one case die on the table Merely opening the trachea is not going to stop the disease but it allows the child to get air and tide over the height of the affection The best indication for the operation is stenosis of the larnyx, and this symptom we do not get when we operate early

The new operation of intubation seems to offer great advantages It can be done early, it is free from the shock of tracheotomy, and above all it does not preclude opening the trachea at a later period It is not yet proved that it can supersede tracheotomy, but he intends giving it a trial at the first opportunity He is not going to give up tracheotomy because of many unsuccessful cases Anæsthesia is not always advisable for the operation as it adds a complication, and besides many cases are so far gone as practically to have no feeling Medicinal treatment has made no advances After much arguing we have come back to the old style of treatment

Practically and clinically speaking a distinction between croup and diphtheria is of no value He has seen cases in the same family some of which looked like croup and some like diphtheria, there may be a difference but he does not think so Where the glands are swollen in either case tracheotomy is less favorable

DR BUSEY said that he more often used quinine in tonic than in antipyretic doses He admits that antipyrin is a better antipyretic than quinine, but owing to the depression which it is likely to cause it is not so applicable to diphtheria as to fevers Dr Thompson says that tracheotomy is not a curative operation and then intimates that he does not believe in medicines The operation admits air which is certainly curative to a limited extent, and this, if for no other reason, justifies the operation From what he says one would suppose that tracheotomy is practically a hap-hazard procedure, he does not supply the symptoms indicating its necessity, nor does he tell us when it becomes imperative There should be some scientific basis for its performance, and there should be some other reason than that of a mere *dernier ressort* At what time is the operation practicable? When we have agreed upon this we will have gained much Some surgeons, as soon as the operation is done, abandon all medicinal treatment, which it is most important to continue and would probably save many cases The croupous membrane which Dr Burnett describes is not a membrane but a pultaceous semi-fluid exudation

DR THOMPSON did not give the indications for tracheotomy as they are well described in the books A depression of the epigastrium below the sternum, and not of the intercostal spaces, is the proper indication for tracheotomy The depression of the intercostal spaces is a later and coarser symptom When he says the operation has no curative effect, he means that it will not stop the spread of the membrane Diphtheria has a self-limited course to run and the longer we put off the fatal issue the greater the chance of recovery From this standpoint tracheotomy is curative It is said that an acute case of diphtheria never gets well after tracheotomy, that a subacute case has a better chance and that a chronic case has the best chance of all The early operation is not curative Every year we have a new remedy which is put forward as a specific, but after a trial we have returned to the old fashioned iron and chlorate of potash mixture

He invariably gives his patient both local and general treatment He uses a large antiseptic spray, with tonics, nourishment and stimulants In his opinion the early operators will, in the long run have a smaller percentage of deaths than the late operators, but they will have performed many unnecessary operations

DR BURNETT remarked that there could be no

doubt as to there being a croupous as well as a diphtheritic membrane in the eye This has been the outcome of many observations by careful observers

Dr J B Hamilton said that the contra indications for tracheotomy were of importance as regards the relation between physician and surgeon In one case which he had been called to operate upon he found a double pneumonia and a capillary bronchitis Considering that the patient was certain to die he refused to do the operation as it would simply bring discredit to the profession The invasion of the larynx is, in his opinion, the indication for operation The operation itself may be fatal when it is followed by pneumonia or bronchitis Hæmorrhagic cases are not relieved by the operation There are some cases in which the hæmorrhage is from the back of the nose that are temporarily relieved by tracheotomy, but death from exhaustion is apt to ensue This complication he thinks is a more common one than is generally supposed He regards the operation as one of the most trying ones in surgery

Dr L Tyler in closing said that Dr Thompson's remarks show that he is in the foremost ranks of one class of thinkers He could not agree with him that tracheotomy was a difficult operation, and without admitting the possession of any special cut-throat proclivities he thought it a most fascinating one While pneumonia following tracheotomy is a remote possibility the very possibility is an indication for an early operation before the lungs have become so congested as to make its sequence more probable We must understand that the operation is a curative one As a *dernier ressort* it may only be productive of euthanasia and anticipatory of a fatal issue from asphyxia Properly speaking there is no such thing as the *croupous* membrane mentioned by Dr Burnett, but rather a *diphtheritic* membrane Croup is a *symptom* of diphtheria, and, in his opinion, the amount of membrane depends upon the extent and degree of the inflammation He agrees with Dr Lovejoy in the opinion that exposure to cold is a cause of diphtheria and he thought he had been able to trace cases to this origin Dr Fernald, in his paper at the previous meeting, had given a strong argument in favor of trypsin as a solvent of the membrane and he would join in recommending its use upon the strength of the results which he had experienced in his case of aural diphtheria

MUNICH [1]

The University—Over crowding in the Profession—Doctors and Rich Wives—Nussbaum, his Work—Extirpation of Struma—Ovariotomy—Winckel—Perineo Plasty—Angerer—Excision of Knee for Tubercular Osteo Myelitis—Heidelmeyer

Dear Dr Fenger—When I arrived in Munich I felt at home, as I attended lectures here during the year 1878 I remained for a whole week, and during this time saw many interesting cases with my former teacher of surgery, Professor Nussbaum, and Professors Winckel and Angerer The Allgemeine Krankenhaus has undergone no change for the better since I attended before The University in this city now numbers 1100 medical students Considering the number of universities in Germany and the large number of students in attendance almost everywhere, it becomes a serious question what is to become of these young men after their graduation The country is now more than supplied with physicians, and if the increase continues for a number of years in the same ratio it is difficult to conceive in what way the medical men are to earn their daily bread

The German government is well aware of the prevailing evil that too many graduates of the gymnasia choose the medical profession, and has taken steps to lead them into other channels by calling their attention to the existing evil through the columns of the public press Only a few days ago Professor Hegar, of Freiburg, informed me that unless a decided change occurred in this direction the medical profession would soon degenerate into a "proletariat" It is well known that even at the present time, in some country towns, doctors will make visits, and even supply the necessary medicine, at half a mark An ignorant "Dienstmann" would look with scorn at anything less than this for carrying your valise from the depot to the hotel We have many cheap doctors in America, but their fees must be considered as royal when compared with such a beggarly sum There is great danger that the same condition will prevail in America at no distant time, unless the medical colleges adopt timely measures to prevent over crowding of the profession by elevating the standard for admission to the study of medicine as well as graduation Nothing will degrade the profession so quickly in the eyes of the public as over crowding In the struggle for an existence men will resort to ways and means which they know are wrong

It is quite a fashion in Europe, among medical men, to marry rich wives in order to keep the wolf from the door, but in my judgment such a course only aggravates the social and professional standing, as wealth acquired in such an easy way brings obligations which are antagonistic to scientific advancement. Unless a man acquires wealth by his own efforts he will seldom find his way into the front ranks of the profession It is better for a man to remain poor as long as he lives, and labor honestly and perseveringly in the interests of his chosen profession, than to be constantly handicapped by a rich wife or her many relatives It is seldom that a rich woman has the good sense to satisfy her ambition in promoting the scientific attainments of her husband, her interests are usually outside of the things that pertain to the profession Only too often her greatest, yes, her only desire is to become a conspicuous figure in society, and as she cannot attend the balls, receptions and theatres alone, the man who married her for her money must do at least what he can to make her happy, and must go along In this way perhaps six evenings in the week are spent, and

[1] By permission of Drs Fenger and Senn.

the books and medical journals, if money is spent for such things, become covered with dust

That this picture is not overdrawn you can verify in your own city, where many of the richest doctors, who ought to occupy prominent positions among their colleagues are not known outside the small circle of friends and acquaintances where they are tolerated only on account of their wealth Science is making such rapid strides that its devotees have absolutely no time for the doubtful pleasures which society can offer The good standing and purity of our profession can only be maintained by admitting into its ranks only men with natural adaptations and an innate love and devotion for the advancement of medical science and its collateral branches

Contrary to several reports that I had received, I found Professor Nussbaum in tolerably good health, and attending to his duties in the hospital with the same regularity and enthusiasm as nine years ago To those who have known him for many years his present condition is a mystery During the Franco-Prussian war he suffered from coxitis, which left one of his hip joints in a contracted anchylosed condition, and since then he has had the misfortune of fracturing several of his bones, and yet after so much suffering and confinement he retains his mental vigor and works with the same enthusiasm as years ago Physically crippled, mentally he is a giant To follow such a man in his work for a few days ought to be enough for any man to stimulate him to follow such an illustrious example Nussbaum has been a hard worker all his life time, and his work bears the stamp of originality His enthusiasm carries him sometimes too far, and yet these extremes have often been productive of a great deal of good He was one of the first apostles of antiseptic surgery in Germany, and his little book (Leitfaden der antiseptischen Wundbehandlung) went through four editions, and did more towards the general adoption of antiseptic principles in the treatment of wounds than all the rest of the German literature combined, but he is familiar, at the same time, with the American and French authors and writers His lectures are always interesting and fascinating, and the lecture room and operating theatre are always crowded with students

During the time I remained in Munich I had the good fortune to see him perform three capital operations, which I will briefly detail The first was an extirpation of a struma The patient was a girl 25 years of age, who had noticed an enlargement of the neck when she was 14 years of age The swelling gradually increased in size until, for the last year, it has given rise to a great deal of discomfort, at times giving rise to suffocating sensations The tumor was about the size of a hen's egg, located directly over the trachea In his remarks on the operation attention was called to the serious consequences which have followed complete extirpation of the thyroid gland as described by Kocher under the title of *cachexia strumi priva*, as well as the results which have been obtained by experimental research It was also stated that since complete excision has been abandoned tetanus had also disappeared from the statistics of struma operations Kocher's incision along the anterior margin of the left sterno cleido mastoid was made, and the tumor well exposed Until the capsule was reached layer after layer was carefully divided and all hæmorrhage arrested With blunt instruments the base of the tumor on each side was reached, and the parts containing the large vessels isolated into sections, and divided between two ligatures By resorting to these precautions the operation was rendered almost bloodless The trachea was found somewhat compressed, but sufficiently firm to retain its shape after the removal of the tumor In cases in which the trachea has become so compressed and atrophied from pressure that after the removal there is danger of suffocation from sudden collapse or flexion, he resorts to amputation of the middle portion of the tumor over the trachea with Paquelin's cautery, so as to leave the part which supports the weakened portion of the trachea Portions of both lateral lobes were left in this case The cavity was filled with iodoform gauze and the skin partially united The iodoform gauze tampon was intended for drainage, and was removed the next day, and the wound at this time was more carefully sutured

The second case was an ovariotomy on a patient 67 years of age The tumor had been noticed two years ago, but had increased in size rapidly for the last few months The abdomen was moderately distended, fluctuating, uterus high, but in the pelvis a number of hard nodules could be felt Attention was called to the difficulty of differentiating in some cases between ascites and ovarian cyst In very obscure cases a positive diagnosis is only possible by an exploratory incision During the operation the temperature of the room was at least 95° F, which made not only the operator but all the students perspire freely The abdomen and pubes were shaved and thoroughly disinfected the day before, and kept covered with a compress saturated with a carbolized solution The abdominal incision was at least four inches in length The tumor was tapped with a large straight trocar and drawn forward into the wound with forceps, and rapidly emptied by incision and crushing of smaller cyst with the hand introduced through the opening The pedicle, broad and fleshy, was compressed with Helferich's constrictor, and the groove made tied with strong double catgut strings, below this point the pedicle was transfixed and tied in two parts, also with catgut Above the first ligature the pedicle was again forcibly compressed between the blades of Langenbeck's forceps and burned off with Paquelin's cautery The cleansing of the peritoneal cavity was done with large, soft sponges wrung out of a warm solution of carbolic acid The abdominal wound was closed with a double row of chromatized catgut sutures and a typical Lister dressing applied

All students are here admitted to laparotomies, and as the balcony above the operating table is usually crowded, it is remarkable that so few of the patients die of septic peritonitis

The third case was another case of ovariotomy, also in an aged person The tumor had been tapped

twice, and each time a large quantity of fluid removed After each tapping a hard mass could be felt in the pelvis The abdominal incision was again made long and led directly into the cyst, as the latter was firmly adherent It took some time to find the point where the two surfaces were adherent The adhesions were separated rapidly, and no attention paid to the oozing which occurred The hard masses which had been felt in the pelvis after tapping proved to be smaller cysts, which were ruptured with the hand introduced through the opening made in the principal cyst As the tumor had no adhesions in the pelvis, it could be readily brought out through the abdominal wound The pedicle was treated in the same manner as in the previous case

Two days later both patients were doing well As the surroundings under which Nussbaum operates are by no means calculated to protect the patients against infection, we must attribute his good results to the careful antiseptic precautions which he follows before and during the operations and the manual dexterity which he has acquired after such a long and extensive experience in abdominal surgery

A good deal of my time in Munich was spent in the lecture room and wards of Professor Winckel Professor Winckel is well and favorably known by his works on gynecology and childbed fever, as well as by his numerous valuable contributions to medical journals and society transactions He organized the German Congress for Gynecology and was elected as its first President He made an extensive tour through the United States and Canada last year, where he made valuable personal acquaintances He is one of the leading gynecologists on the Continent, and has a better and more intimate acquaintance with the literature of his specialty than any other specialist He is now writing a text book on obstetrics, which will undoubtedly take the place of the most popular text-book on the same subject written by the lamented Carl Schroeder Professor Winckel has been a teacher almost since his graduation, and many of his pupils only a few years younger than himself are now distinguished surgeons and physicians I was astonished when he told me that Professor Schoenborn, now of Wurzburg, was one of his pupils, as the latter looks much older than his teacher Winckel is a systematic worker, and never fails to make good use of his vacations to benefit his bodily health, and this undoubtedly explains his excellent physical condition He is a great traveler and a most accurate observer He is a hard student, a pleasant and forcible writer, a fascinating and enthusiastic teacher, a splendid diagnostician, and a brilliant and beautiful operator He is a most valuable member of the Faculty, and will make his department one of the most attractive and successful in Europe In his obstetrical wards the most scrupulous cleanliness prevails, and wherever necessary full antiseptic precautions are practiced, consequently indigenous cases of sepsis are almost unknown His laparotomies are attended only by a few students, who must give proof that they have not been recently exposed to septic germs I witnessed an ovariotomy in his wards which was done under strict antiseptic precautions and with a neatness and dispatch which would be difficult to excel The patient recovered without a single untoward symptom

His private course on operative gynecology is unsurpassed by anything of this kind The entire organs of generation of the female are removed from cadavers, preserved in an aqueous solution of corrosive sublimate and kept ready for use The soft parts are placed in a Schultze's phantom and attached in such an accurate manner that the normal relations are preserved On such specimens the student is required to perform all the more important operations in gynecology under the immediate supervision of his teacher Some of the students assist in the operations When I was present the students were all arranged around three tables with as many operators, while Professor Winckel walked from place to place and directed the work All teachers of gynecology should imitate this method of teaching, as it is the only way which will furnish adequate material for the different operations, and which will familiarize the students with the details of the most important operations

I was very much interested in a case of perineoplasty which I witnessed The laceration had extended into the rectum, and after vivifying the retracted margins of the rectal tear, coaptation was secured with silkworm-gut sutures passed through the entire thickness of the recto-vaginal wall and tied on the vaginal side The perineum was sutured with the same material after Hegar's plan Professor Winckel has performed this operation in many cases in this manner, and has never observed a recto-vaginal fistula after the operation The recto-vaginal sutures are allowed to remain for several weeks

Professor Angerer is the successor of Professor Helferich now of Greifswald, and has charge of the polyclinic in the Reisingerianum The operating room holds about 100 students, and is daily crowded from 11 to 12 A large clinical material collects here, and many important operations are performed, as the institution contains a few beds where patients can remain for a limited length of time Angerer is a good lecturer and an expert operator

Among a number of operations that I saw here I was most interested in a case of excision of the knee-joint in a little boy suffering from tubercular osteomyelitis of the inner condyle of the femur, and consecutive fungous synovitis of the joint On a previous occasion a tubercular spot had been removed from the inner tuberosity of the tibia The joint was opened by a transverse incision and division of the ligamentum patellæ When the patella was reflected it was found that the primary focus in the tibia had not healed, but had extended into the joint, the internal condyle on opposite side of joint was the seat of a similar depot, also in communication with the joint But the most remarkable condition was seen in the joint and recesses underneath the patella and quadriceps muscle Only half of the joint was the seat of infection and secondary fungous proliferation, as the remaining portion of the joint, corresponding to the external condyle of the femur and the external tuberosity of the tibia, remained in

a perfectly healthy, intact condition, being separated from the diseased portion by a partition of firm connective tissue This is the condition which had been described to me by Professor Koenig a few weeks before, in which nature makes an attempt to localize the extension of tubercular processes, even in joints, by throwing out a wall of cicatricial tissue Portions of the condyle and tuberosity were removed with the saw, and the healthy portion of the joint was left intact The tendon of the patella was sutured and the wound closed, except at points where bone was removed, where tubular drainage was established A copious dry sublimated dressing was applied and the limb placed upon a posterior splint

I suggested to Professor Angerer after the operation that, under similar favorable circumstances, it would be advisable to split off the remaining portion of the internal condyle to draw it downward until it could be brought in apposition with the head of the tibia, where it could be retained with one or two aseptic bone-nails Such a modification would secure a better support for the tibia, and prevent a tendency to the formation of a genu valgum during the reparative process

Professor Angerer drills his students thoroughly in surgical diagnosis, and makes them familiar with important details which are usually ignored in the larger clinics In connection with the polyclinic is a small laboratory where, under the direction of Professor Angerer, bacteriological studies are made and specimens from the clinic examined under the microscope It is such a laboratory as I have urged should exist in connection with every chair of surgery, for the purpose of developing and teaching surgical pathology Mr Heilmeyer, who works in this laboratory, is an expert in preparing and mounting specimens, and as the sale of his slides is his principal source of income, he deserves the patronage of all who wish to promote the welfare and happiness of an humble but devoted promoter of the science of medicine

During my stay in Munich I enjoyed the hospitality and friendship of Professor Winckel, and I fear I shall not be able to reciprocate his kindness unless he undertakes another tour through the United States, an event which would be looked for with pleasure by a host of his American friends N SENN

LETTER FROM VIENNA

(FROM OUR OWN CORRESPONDENT)

Etiology and Treatment of Asthma caused by Polypi and Catarrhs—Dr Pawlik—Dr Ehrendorfer

At the last meeting of the Vienna "Doctoren-Collegium" Regierungsrath Prof Schnitzler made a valuable communication on the etiology and treatment of asthma He above all wished to direct the attention to those cases of asthma which were caused by polypi of the nose and by nasal catarrhs, and which had been neglected for so long a time Diseases of the nose were a frequent cause of asthma, and in most of cases polypi of the nose, and among these especially mucous polypi, gave origin to bronchial asthma Often already a simple chronic nasal catarrh was a sufficient cause for producing asthmatic disturbances of a high degree These disturbances, however, did not develop owing to narrowing or obstruction of the nasal cavities, and neither by the continuation of the catarrhal inflammatory process to the mucous membrane of the nose or the pharynx, etc , as was suggested by some authors They were of a reflex nature, and due to the irritation of the nasal branches of the fifth nerve, and sometimes also the olfactory nerve, which, on the other hand, produced a reflex irritation of the vagus and the phrenicus nerves This irritation produced the bronchial asthma with all its known symptoms Hence, according to the opinion of Prof Schnitzler, the asthma was an innervation disturbance of the respiratory process, being produced by reflex, and the asthma resulting from polypi of the nose or chronic nasal catarrhs was particularly to be looked upon as a reflex neurosis taking its origin in the nasal nerves The reflex irritation of the vagus first led to a spasm of the bronchi, which was in most of cases also followed by a spasm of the diaphragm owing to the irritation of the phrenicus At the same time vasomotor disturbances of the respiratory organs supervened—hyperæmia and augmented secretion of the bronchial mucous membrane—and the complex of the symptoms met with in cases of asthma was complete But all the nerves mentioned above were not irritated in all cases of asthma, and all the organs which depended on them were not always affected either, sometimes the vaso motor disturbances, and in other cases the spastic conditions, prevailed, and this fact accounted for the different explanations of the nature of asthma, each of which was justified, according to the opinion of Prof Schnitzler

Prof Schnitzler then discussed the treatment of bronchial asthma, and especially that which was produced by polypi of the nose and nasal catarrhs, at full length In cases of polypi of the nose, he had always obtained recovery of the asthma by removing the polypous affection, either by operation or by galvano caustic treatment Before the asthmatic attack, he had often been able to cut it short by brushings of the nasal mucous membrane with a from 5 to 10 per cent solution of cocaine He had also obtained good results with the administration of the iodide of potassium in combination with chloral hydrate During the attack, chloral hydrate (administered by the mouth or by means of clysters), and injections of morphine proved as the proportionately most efficient agents, but their effect was nevertheless not so constant as had been stated by some authors The fumigations with saltpetre, stramonium, pyridin, etc , proved in some cases to be efficient, in others they failed to do so As to amyl nitrite, the nitrate of silver, and nitroglycerine, they had a better effect in cases of cardial asthma than in bronchial asthma Prof Schnitzler passed an interesting and critical review of all the remedies which had been recommended in the treatment of asthma—the agents for precipitating the secretion, the climate, and pneumato therapeutics, etc, and objected to the efficiency of most of them, a fact which is very plausible, considering that the known Vienna laryngologist was

educated in the nihilistic Vienna school of Skoda and Oppolzer, of whom he is one of the worthiest disciples

Dr Pawlik, Docent of Obstetrics and Gynecology in the Vienna Medical Faculty, has been elected an ordinary Professor of these subjects at the Medical Faculty of Prague, (with Bohemian language) [There are in Prague two Medical Faculties, a German and Bohemian one]

Dr Ehrendorfer, late Assistant of Prof Spaeth in the chair of Obstetrics and Gynecology, has been named as ordinary Professor at the Medical Faculty of Innsbruck (in Tyrol)

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Cocaine in Staphylorrhaphies and Plastic Operations—Retention of the Placenta after Miscarriage

Dr Ehrmann, of Mulhouse, Corresponding Member of the Paris Academy of Medicine, proposes the employment of cocaine as an adjuvant in certain staphylorrhaphies, whether simple or complemental After having related the cases that came under his notice, Dr Ehrmann concludes that the analgetic effect determined on the soft palate by a solution of cocaine is scarcely more than superficial, and that this local anæsthia, really precious for certain cases can never replace chloroform in palatoplasty, nor even in staphylorrhaphy properly speaking, complete, in that which necessitates muscular sections, or detachments of the palatine bone The cases where, in congenital fissures, the division is practised on only one portion of the soft palate where therefore a simple apposition is sufficient for union, these cases are assimilable to complemental or partial staphylorrhaphies, but they are very rare In 50 subjects on whom Dr Ehrmann performed plastic operations on the palate for congenital divisions, he met with only two who presented this arrangement

In a very interesting paper by Dr Budin, an Agrégé of the Faculty of Paris and Hospital Accoucheur, which was read before at the Academy of Medicine, on the retention of the placenta after miscarriage, the author, in response to discussions which have lately taken place at various learned societies observed that two principal complications may supervene in these cases, hæmorrhage and septicæmia Against these accidents, the question is asked, whether manual and instrumental intervention are rational or necessary To accept these hypothesis, it must be demonstrated 1 That the retention of the placenta is really a source of frequent accidents 2 That all digital and instrumental manœuvres which are resorted to in such cases present any danger

To the first question, Dr Budin responds by using facts observed by him at the Charity and at the Maternity Hospitals Of a total of 210 cases of miscarriage (57 at the Charity, 153 cases at the Maternity) there were 46 cases of retention of the placenta, or 22 per cent At the Charity there were no cases of hæmorrhage, at the Maternity 2 cases of slight hæmorrhage occurred at the moment of the removal of the placenta. Septic accidents were almost nil There was only one death, that of a woman who entered the Maternity with bronchitis and fever, and in whom after a miscarriage the placenta was expelled after 60 hours and the patient died of intercurrent pneumonia 15 days after the miscarriage Therefore, of 210 cases of miscarriage accompanied 46 times by retention of the placenta, there was only one death the cause of which could hardly be imputable to the miscarriage As regards digital, instrumental or other manœuvres, they are inefficacious or dangerous Different accoucheurs have observed severe hæmorrhages, endometritis, pelvic abscesses and even death resulting from interventions of this kind Expectation and antisepsy are recommended in these cases A B

NECROLOGY

JOHN WADHAMS RUSSELL, M.D

John Wadhams Russell, of Mount Vernon, Ohio, was born in Canaan, Litchfield County, Conn , on January 28, 1804 His father, Hon Stephen Russell, was repeatedly elected a member of the Connecticut Legislature, and his grand father, Jonathan Russell, commanded a brig under General Lafayette's letters of marque in 1778 Dr Russell's mother was Sarah Wadhams, of Goshen, Conn His education until his thirteenth year was received at the common schools of Litchfield, whither his father removed in 1808 Then he was sent to Morris Academy, and under Rev Truman Marsh pursued his studies and was prepared for, and admitted to Hamilton College in 1821 He pursued his classical studies with the Rev Mr Langdon, of Bethlehem, Conn , one year, as his impaired health would permit, and in the fall of 1823 went South He took charge of an academy at Red Bank, Colleton District, S C , six months and there commenced his professional studies with Dr Sheridan, a scientific and noble hearted Quaker Returning to Connecticut he attended the Medical lectures at Yale College one course, and then going to Pittsfield, Mass , there attended the lectures in Berkshire Medical College Subsequently, going to Philadelphia, he was a private pupil of Dr George McClellan, and was graduated from Jefferson Medical College in 1827 Returning to Litchfield he there began the practice of his profession, and remained there for one year, during which time he delivered a course of lectures on anatomy and physiology to a private class of young men In 1828 he removed to Ohio, and began practice at Sandusky City, where he remained but a few months, when he moved to Mount Vernon, in Knox County He was a delegate to and member of the Centennial International Medical Congress which met in Philadelphia in 1876 At this meeting of the International Medical Congress Dr S D Gross said, "it gave him great pleasure to introduce to his medical brethren, his esteemed friend and classmate Dr Russell whose extreme modesty *alone* prevented him from being the leading surgeon of the land "

In 1828 Dr Russell married Eliza, daughter of the Hon William Beebe, of Litchfield, Connecticut

She died in 1871, having been the mother of five children In 1872 Dr Russell married, in San Francisco, Ellen M Brown, daughter of Joseph Brown, Esq She died on October 14, 1879

Dr Russell was a man of indefatigable industry During his life he probably performed more physical and mental labor than the majority of his contemporaries, in or out of the profession His work did not begin with the rising or close with the setting sun, and the day usually allotted to rest found him actively engaged In his early practice he visited his patients on horseback While on a professional trip near Gambier in 1836 his horse fell on the ice and injured his knee-joint, which resulted in false anchylosis and compelled him to use a crutch afterwards For a like disability many would have abandoned an active practice, but with him it had no effect, only to intensify his zeal and change his mode of travel Mules were called into requisition, and with two of these animals and a carriage he scaled the hills of Knox and the adjoining counties for half a century During the 60 years of his professional life, his instruction was sought by not less than 300 young men preparing to enter the medical profession He was a most capable and thorough office preceptor He imparted instruction to his pupils by recitations, dissections, demonstrations, and oral instruction, and by his own exemplary conduct taught them medical ethics He elicited the profound respect and admiration of his pupils, and inspired them with enthusiasm in their studies In his journeys to his patients he would take a student, and his text-book, conduct the recitation *en route*, and when darkness or other causes intervened no time would be lost, for now came the memorable quiz over past work, and for which he was truly famous That his office was an uncomfortable place for a lazy student, and that the doctor had no patience with a man who would not work his brain is shown by an extract from a letter to the late Dr William Morrow Beach, of London, O "For fifty-nine years it has been my happy lot to serve the afflicted conscientiously, faithfully, and I wish I might add judiciously This I cannot always say I have prayed for wisdom, and would advise the same to my juniors The great sin in our profession is *indolence* A man is responsible not only to do as well as he knows, but to use his faculties to know what to do"

It was in general surgery that he took most interest, and found most pleasure He regarded anatomical knowledge as the true basis of all success and skill in surgery Living in a county where it is necessary to be a general practitioner in medicine and surgery, he performed most of the so-called capital operations, such as lithotomy, herniotomy, and all the most important amputations, except that of the hip-joint, and many of the more delicate operations as that for cataract, etc, and with almost uniform success He was careful to keep pace with the advances of medicine In all matters he faithfully followed his convictions of duty regardless of the sacrifice of self which such a course might require He was tendered the Professorship of Surgery in several Medical Colleges, but declined them all, preferring to remain in private practice He was an active Christian, ever ready to perform those duties which the love of Christ developed upon him He had an hypertrophied prostate for eighteen years, the pain and other resulting inconveniences of which he bore with fortitude and without a murmur Retention of urine and uræmia caused his death on March 22, 1887, at the advanced age of 83 years He died as many had predicted, "in the harness," having prescribed for patients up to within forty-eight hours of his death

F C L

INTERNATIONAL CONGRESS.

SECTION OF LARYNGOLOGY

This Section will meet on Monday, September 5, 1887, at 2 o'clock P M

OFFICERS

President, Wm H Daly, M D, Pittsburgh, Pa

Vice-Presidents, Mr Lennox Browne, F R C S E, London, England, Dr J Baratoux, Paris, France, Dr Bouchet, Paris, France, Dr J Charazac, Toulouse, France, Dr Karl Dehio, Dorpat, Russia, Dr J J Kirk Duncanson, Edinburgh, Scotland Dr C M Desvernine, Havana, Cuba, Dr Jos Gruber, Vienna, Austria, Dr J H Hartman, Baltimore, Md, Dr Prosser James, London, England, Dr B D Moura, Paris, France, Dr O Rosenbach, Breslau, Germany, Dr E L Shurly, Detroit, Mich, Dr A Schnee, Nice, France, Dr John Schnitzler, Vienna, Austria, Dr G V Woolen, Indianapolis, Ind, Dr M'Niel Whistler, London, England, Dr F Laborde De Winthuyssen, Sevilla, Spain, Dr J O Roe, Rochester, N Y

MEMBERS OF COUNCIL

Dr J Dennis Arnold, San Francisco, Dr H Blaikie, Edinburgh, Scotland, Dr S N Benham, Pittsburgh, Pa, Dr W E Casselberry, Chicago, Dr Lester Curtis, Chicago, Dr H H Curtis, New York, Dr Andrew J Coey, Chicago, Dr Richard Ellis, Newcastle-on-Tyne, England, Dr Herman E Hayd, Buffalo, N Y, Dr Theodore Herring, Warsaw, Poland, Dr E Fletcher Ingals, Chicago, Dr Geo Mackern, Buenos Ayres, Argentine Republic, Dr M C O'Toole, San Francisco, Dr S W Pearson, Baltimore, Md

American Secretaries—Wm Porter, M D, St Louis, Mo, D N Rankin, A M, M D, Allegheny, Pa

German Secretary—Dr Ottaker Chiari, Vienna, Austria

French Secretary—Dr E G Moure, Bordeaux, France

DISCUSSIONS

The following subjects have been selected for special discussion

1 The Diagnosis and Treatment of Catarrhal Disease of the Antrum of Highmore To be introduced by Dr Lennox Browne, London, Eng

2 Epistaxis To be introduced by Prof E Fletcher Ingals, Chicago, Ill

3 The Treatment of Laryngeal Papillomata To be introduced by Prof W E Casselberry, Chicago, Ill

4 Recurrent Hæmorrhages of the Upper Air passages Introduced by Dr Wm Porter, St Louis, Mo

5 The Diagnostic Differentiation of Recent Tuberculous, Specific, and Rheumatic Laryngeal Disease Introduced by Dr E L Shurly, Detroit, Mich

PAPERS

MONDAY, SEPTEMBER 5—FIRST DAY

Section meets at 2 o'clock, P M

F B Eaton, M D, Portland, Oregon The present Status of the Galvano-Cautery in the Treatment of the Diseases of the Upper Air-passages, illustrated by improved Forms of Electrodes and Description of Cases

Richardson Gray, M D, Orange, N J The Galvano Cautery in the Treatment of Diseases of the Nose and Throat, with description of perfect Battery

H H Curtis, M D, New York Surgery of the Nasal Septum and Turbinate Bodies

John North, M D, Keokuk, Iowa The Influence of Disease of the Mucous Membrane of the Upper Air passages upon the Sympathetic Nervous System

Richard H Thomas, M D, Baltimore A Contribution to the Causes and Treatment of so called Hay Fever, Nasal Asthma, and allied Affections, considered from a clinical standpoint

I P Klingensmith, M D, Blairsville, Pa. Hay Asthma

D N Rankin, M D, Allegheny, Pa. Some Remarks on the History of Rhinology

J Baratoux, M D, Paris, France Le catarrh naso pharyngien

TUESDAY, SEPTEMBER 6—SECOND DAY

Section meets at 2 o'clock P M

O Rosenbach, M D, Breslau, Germany Ueber nervosen Hustens und seine Behandlung

A W Orwin, M D, London, Eng Lupus of the Larynx

Geo Mackern, M D, Buenos Ayres, Argentine Republic The Earlier Manifestation of Malignant Disease of the Larynx

F Laborde De Winthuyssen, M D, Sevilla, Spain Le sulfure de calcium dans le traitement de la diphthérie

R N Wolfenden, M D, London, Eng Trachecele

Paul Koch, M D, Luxembourg, France Parasites of the Pharynx and Larynx

A Cartaz, M D, Paris, France Some Rare Accidents in Tracheotomy

F Massei, M D, Naples, Italy Primary Erysipelas of the Larynx

WEDNESDAY, SEPTEMBER 7—THIRD DAY

Section meets at 2 o'clock P M

J A Stucky, M D, Lexington, Ky Clinical Report on the Treatment of Laryngeal Phthisis

C M Desvernine, M D, Havana, Cuba The Longitudinal Tension of the Vocal Cords, its Physiology and its Derangements

F Moura, M D, Paris, France The Classification of the Muscles of the Larynx

Ephraim Cutter, M D, New York Relations of Phonation to Cantation, with some practical deductions

Carl Seiler, M D, Philadelphia A Case of complete Stenosis of the Larynx, in which Articulation was unintelligible, with complete Restoration of the Voice by Surgical Procedure

E Fletcher Ingals, M D, Chicago, Ill Chronic Rheumatic Laryngitis

H E Hayd, M D, Buffalo, N Y Sarcoma of the Larynx

THURSDAY, SEPTEMBER 8—FOURTH DAY

Section meets at 2 o'clock P M

W E Casselberry, M D, Chicago Ill Nasal Fibromata

John O Roe, M D, Rochester, N Y Chorea Laryngealis

M J Stern, M D, Philadelphia. Intubation or Tracheotomy

Bouchet, M D, Paris, France Tubage of the Larynx

Carmalt Jones, M D, London, Eng The Action of the Epiglottis in Swallowing

M F Coomes, M D, Louisville, Ky The Deleterious Effects of Tobacco on the Throat and Nose

F Semeleder, M D, Mexico Twenty years of Laryngological work in the City of Mexico

Geo Mackern, M D, Buenos Ayres, Argentine Republic The Local Treatment of Diphtheritic Membrane by Carbolic Acid and Iodized Steam Inhalations

FRIDAY, SEPTEMBER 9—FIFTH DAY

Section meets at 2 o'clock P M

A Schnee, M D, Nice, France Cure of Papillomata Laryngis

J H Hartman, M D, Baltimore Cystic Tumors of the Epiglottis, their Pathology and Treatment, with report of Cases

M C O'Toole, M D, San Francisco The Laryngologist, what should constitute his special practice?

J O'Dwyer, M D, New York The Treatment of Chronic Stenosis of the Larynx and Trachea by Intubation

A B Thrasher, M D, Cincinnati, O Resorcin in the Treatment of Nasal Catarrh

Mr Lennox Browne, F R C S E, London, Eng Recent Views as to the Pathology and Treatment of Tuberculosis of the Throat and Larynx

A J Coey, M D, Chicago, Ill The Relation of Asthma to Nasal Irritation

---

SECTION IV —OBSTETRICS —A meeting of the officers of this Section, including the Vice-Presidents and Members of the Council, will be held in the Georgetown Medical College, corner of 10th and E Sts, Washington, D C, on *Saturday, September 3d, 1887*, at 3 o'clock, P M, to consider and arrange the work and details for the Sessions of the Section during the ensuing week

SECTION XVI —MEDICAL CLIMATOLOGY AND DEMOGRAPHY —There will be a meeting of the officers of this Section in the Cornwell building, Pennsylvania avenue, between 14th and 15th streets, at 4 o'clock, P M , *Saturday, September 3d*, for conference respecting the business of the Section Officers of the Section should state whether they can be present, and advise Dr Denison, through the office of the Secretary General, 1421 G St , N W , Washington, D C , of their contemplated post-office address in that city

ALBERT L GIHON, M D , *President*

SECTION OF DISEASES OF CHILDREN —To the list of papers published last week should be added after the paper by Mr Noble Smith, "The Principles of Treatment of Club Foot, partly demonstrated by the Exhibition of Apparatus" By Will E Blackwill, London, England

SECTION ON OBSTETRICS —The following should be added to the list of papers already published

Professor W S Stewart, M D , Philadelphia, 1 Improved Obstetrical Forceps with Parallel Handle 2 The Importance of Careful Diagnosis of Pregnancy, with the History of a Case of Retroflexion of the Gravid Uterus, Labor at Term

E P Christian, M D , Wyandotte, Mich , The Proportion and Causes of Still-births

REDUCED RAILWAY RATES IN CANADA —The Inter-Colonial Railway Co will return free of charge members who pay full fare coming over its roads The Canada Atlantic Railway Co , the Northern and Northwestern Railways, and the Napanee, Tamworth and Quebec, will return members for one-third fare who pay full fare coming

J W H LOVEJOY, M D , *Chr'mn Com on Trans*

HOTEL ACCOMMODATIONS IN WASHINGTON —The attention of those who have not completed their hotel arrangements during the Session of the Congress is called to the list of hotels on page 10 of THE JOURNAL Advertiser

TO THE CONGRESS FROM THE WEST —Members of the Congress can leave St Louis, Mo , any morning or evening in Buffet and Pullman palace cars, without change to Washington, via the "Air Line," Chesapeake and Ohio, and Midland Railroad Members can return by Midland R R , or from Old Point Comfort Certificates will be honored at either place and one third of full fare will be charged for return tickets Arrangements have been made to give ample time to visit Virginia Beach, Norfolk, Portsmouth, Old Point Comfort, Richmond, Natural Bridge, Luray Caverns, White Sulphur Springs, Louisville Exposition and Mammoth Cave Reduced rates may be obtained at all hotels to members and friends For particulars apply to C Kennedy, "Air Line," St Louis, Mo , or D G Edwards, C & O R R , Cincinnati, Ohio

Special trains will be run from Chicago via the Baltimore & Ohio Railway, leaving Chicago on September 3, at 3 30 P M Full information concerning these trains may be found on page 9 of THE JOURNAL Advertiser

MISCELLANEOUS

A CAUSE OF TYPHOID FEVER —Discussing the distribution of typhoid fever in Oldham, Dr Niven, the medical officer of health, refers to the well known tendency of this disease to prevail in the colder rather than in the warmer months In the case of his district he interprets it by explaining that there is a general influence in operation which is for the most part compared with influences acting specially in the winter months That general influence he describes as either the admission of sewer air into houses by means of defective drain arrangements, or the action of polluted subsoil water, or the two combined Open doors and windows in summer reduce to a minimum the evils thus resulting But in the winter, injurious emanations are drawn into dwellings by the aid of internal warmth and of fires, and the foul air is penned in by reason of closed doors and windows This explanation has often been referred to by various officers of health, and the circumstances described must be regarded as having an important bearing both upon typhoid fever and other conditions of health Ventilation of houses is as much needed in winter as in summer, and we should like to see it by law which requires every house to be built on a site covered with a layer of good cement concrete everywhere adopted and carried out By such means alone can the suction into dwellings of subsoil air, which is always open to suspicion, be prevented —*Lancet*, July 23, 1887

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM AUGUST 13 1887, TO AUGUST 19, 1887

Col J H Baxter, Chief Medical Purveyor, ordered to proceed from Washington, D C , to New York City, on public business, and on completion thereof, to return to this city Par 5, S O 187, A G O , August 13, 1887

Major W D Wolverton, Surgeon, Washington Bks , D C , granted leave of absence for twenty days Par 3, S O 171, Div Atlantic, August 16, 1887

Capt Charles B Byrne, Asst Surgeon, Washington Bks., D C , granted leave of absence for one month, with permission to apply for an extension of one month Par 4, S O 171, Div Atlantic, August 16, 1887

Capt George F Wilson, Asst Surgeon, granted leave of absence for fifteen days S O 78, Dept of Dakota, August 8, 1887

First Lieut William D Dietz, Asst Surgeon, granted leave of absence for two months, with permission to apply for an extension of one month Par 7, S O 189, Hdqrs. of the Army, A G O , August 16, 1887

First Lieut W D McCaw, Asst Surgeon, relieved from temporary duty at Ft Riley, Kans , and ordered to his proper station, Ft Leavenworth, Kans Par 3, S O 84, Dept Wisconsin, August 15, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING AUGUST 20 1887

Medical Inspector S Robinson, placed on retired list

P A Surgeon J E Gardner, detached from Naval Hospital, Norfolk, Va , and ordered to the Fish Commission Str "Albatross"

Asst Surgeon Wm Martin, ordered to Naval Hospital, Norfolk, Va

Surgeon W K Van Reypen, appointed Medical Inspector from August 16, 1887

P A Surgeon M H Simons, appointed Surgeon from August 16, 1887

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING AUGUST 20 1887

Surgeon W H Long, leave extended six days on account of sickness August 13 1887

Surgeon C S D Bessenden, granted leave of absence for thirty days August 19, 1887

Surgeon John Godfrey, granted leave of absence for thirty days August 17, 1887

P A Surgeon A H Glennan, granted leave of absence for thirty days August 18, 1887

Asst Surgeon W P McIntosh, granted leave of absence for twenty five days, on account of sickness August 17, 1887

ORIGINAL LECTURES.

LECTURE ON THE TREATMENT OF TYPHOID FEVER

BY PROF DR HERMANN von ZIEMSSEN,

DIRECTOR OF THE MEDICAL CLINIC IN MUNICH

(*Concluded from page 261*)

We now come to the physical and pharmaceutical methods and measures used in the treatment of typhoid fever Speaking generally, the physical measures are to be placed above the pharmaceutical, though the latter cannot be dispensed with Had we a specific means of rendering harmless the cause of the disease, of course our endeavor would be to administer it at the beginning of the disease But we have no specific which acts in the same way as quinine in intermittents or salicylic acid in acute rheumatism The only drug to which we can ascribe a kind of specific action, is calomel, perhaps on account of its entire or partial change, by the chlorine of the sodium chloride in the intestinal juices, into corrosive sublimate I give calomel in 3 doses of gram 0 5 in two hours, and then obtain a number of thin grass- or moss green (calomel) stools and a considerable reduction of temperature, which often goes down to normal and lasts about 12 hours These are the primary effects of calomel

The secondary effects of the drug consist in a modification of the intensity of the infectious condition, as Liebermeister has shown Those cases which are early subjected to treatment by calomel generally run a somewhat milder course than those in which it is not used, or only used later, milder both in regard to the fever as well as in the local affection of the intestine The earlier calomel is given the better—best at all events within the first 5 days, but it should be used during the first week The action of calomel (or the sublimate) is very possibly a sterilizing one on the specific bacteria vegetating in the intestine, but beyond this we know nothing more exact An abortive action of calomel, such as has been claimed by Wunderlich, has not been shown Griesinger, then Baumler, and more recently Weil, have shown that neither the mortality is lessened by the use of calomel, nor the number of aborted cases increased, and that no other properties belong to calomel than those of a mild, non irritating evacuant which reduces temperature Against the assertions of some authors that we have to do here only with a simple eccoprotic effect, is our experience that the action of calomel on the temperature and the local intestinal affection is seen when active diarrhœa already exists, and there need be no further discussion as to the eccoprotic action The attempt to fix the hypothetical specific action by long continued calomel treatment, and to force a true abortive calomel treatment, has been made at different times, but without success I have treated a series of cases with small doses of calomel for a long time, after having begun treatment with larger doses, but without obtaining any strikingly good result So, too, the sublimate treatment of typhoid fever has been without good results

Next to calomel, baths deserve the greatest consideration On his admission to the hospital, if his condition is not too bad, the patient receives a warm bath to cleanse the skin and remove possible parasites Then the course of the temperature for 12 or 24 hours is determined by bi hourly measurements, best taken in the rectum, because the patient can better endure the short duration of the measurement here (2 or 3 minutes) than the 15 or 20 minute measurements in the axilla, and even in private practice rectal measurements are but seldom objected to In private practice, meanwhile, the necessary directions and regulations as to the bath and care of the patient may be given, the sick-room furnished with a change of beds, and everything in the way of linen, vessels, etc, prepared for a long sickness

When the normal temperature curve is determined it is best to begin immediately with the baths, first with luke warm baths at 86°–81 5° F, 15 minutes long, and with continual stirring of the water and washing over of the upper part of the body, so far as it is not dipped into the water The higher the temperature goes, the more severe the cerebral affection, the muscular weakness, and the intestinal affection, so much the cooler must be the bath, though for several years I have never given a bath lower than 63 5°, that is, below the temperature of the room In the hospital the bath-tub is placed by the patient's bed, with a screen around it, and the patient is lifted into it It is necessary to renew the water in the bath only once in 24 hours

In many cases the bath is given only luke-warm (not under 75°) during the whole course of the illness, beginning each time with a temperature of 88 2°–86°, and while the patient sits in the bath the

[1] Translated by permission of author and publishers from advance sheets by Wm G Eggleston M D, of Chicago

and 7, given in wafers I seldom gave more than 2 grams, and frequently, as in women with weak constitutions 1 5 and 1 gram was given in the third week

Of late years Knorr's antipyrin has completely supplanted quinine as an antipyretic in my practice In doses of 5 grams (best given in doses of 2, 2, and 1 hourly in the evening after 6 o'clock) it is a much more certain antipyretic, and is entirely free from undesirable after effects It is only infrequently that vomiting is caused by it, the sweating is moderate, sleep usually undisturbed, and the euphoria in the morning is in the highest degree pleasant The patients are perhaps somewhat apathetic, but have nothing to complain of The temperature falls from 2° to 4° C , and remains low for a tolerably long time, certainly as long as with quinine The rubeoloid exanthem so frequently observed is of no significance The prompt action on the rectum is also pleasant, in the same or somewhat larger doses I have seen vomiting repeatedly after clysters of antipyrin, and others have observed the same effect I have now used antipyrin in several hundred cases, and always with satisfaction, and can recommend it as a most trustworthy antipyretic

Thallin is also a very good antipyretic, as I have shown by a series of cases, but it seems that it cannot take the place of antipyrin Under its use I have repeatedly observed the same shivering with the reascension of the temperature as with kairin It is in favor of thallin that it acts in comparatively small doses We use about one-fourth as much as the dose of antipyrin— 25—given 4 or 5 times

Antifebrin, which we have used since the first notice of it from Kussmaul's clinic, and in comparison with antipyrin, is a valuable antipyretic Our experiments with it have given extraordinarily favorable results Its action in fever is very certain, the secondary effects are but slight and temporary, and its administration is followed by great euphoria and decided improvement in appetite The drug has the very great advantage that it acts in such small doses (one-fifth or one fourth the dose of antipyrin), and that it is so cheap

Kairin and salicylate of soda are perhaps too antiquated to be considered antipyretics

The treatment of individual symptoms, symptom excesses, plays an important part in the treatment of typhoid fever It has already been said that so severe an infection of so great length and of such deleterious action on the nutrition of the animal cells must have a corresponding amount of organic disturbances in its course, each one of which may threaten life, and require skill on the part of the physician What cell territories are affected by the destructive influences of the infection—the typhoid bacilli and their products—whether the brain, the kidneys, the parotid gland, the bronchial mucous membrane, the pulmonary tissue or the skin, depend upon factors which are only partly known to us Of how great importance are proper innervation and circulation is shown by the good effects of baths and rubbing on the nutrition of the skin during typhoid fever

The cerebral symptoms, headache, oppression, vertigo, generally call for the permanent use of ice-bladders By far the greater number of patients, and in all in whom an antipyretic treatment gives a sensorium, find the effect of the ice-bladder very grateful, and call for them after they have seen their effect But there are some patients, especially those of a nervous nature, to whom permanent cooling of the head is unpleasant In such cases the subjective feelings of the patient must be taken into consideration

Sleeplessness, restlessness and tossing at night are best controlled by a moderate dose of morphia, I usually begin with a dose of 1 centigram, and afterwards go up to 1 5 or 2 cgm I have never seen such after effects as hyperæmia of the brain, increase of headache, etc Most patients praise the peaceful rest which morphine gives them

For very active delirium with bodily unrest, the condition which gave rise to the old term *febris nervosa versatilis*, luke-warm and warm baths, as recommended above, should be given in the evening and the early part of the night If these do not produce the desired effect a hypodermatic injection of morphine should be given In the severe and more torpid type of cerebral troubles, which years ago was known as *febris nervosa stupida*, cold baths with short douches are best, and act better than morphine in giving a few hours of peaceful sleep

Cardiac weakness is *the* phenomenon which is of most dangerous import, and demands the greatest attention on the part of the physician and attendants This condition is always to be expected when a patient comes into an attack of typhoid fever with a weakened heart, as, for example, after an attack of endo-myo-pericarditis, in cases of valvular disease, dilatation of the ventricles, muscular weakness from strain, from intemperance, etc The danger may be recognized early by the comparative high pulse rate at the beginning As a rule the pulse then becomes smaller, and the temperature of the skin falls in consequence of the insufficient filling of the peripheral arteries High blood temperature with cool extremities, very frequent, small and irregular pulse, pale or pale livid color of the skin, these symptoms show a most significant complex, and demand the most energetic use of stimulants and the most careful overlooking of the whole dietetic arrangement

As regards drugs in this condition I give decided preference to camphor, because it can be given subcutaneously in almost unlimited quantities and as often as desired without the slightest local troubles The action of subcutaneous injections of oleum camphoratum fortius (1 part of camphor to 5 of olive oil) from 2 to 5 syringefuls, is most satisfactory and continues for a considerable time In a few threatening conditions 1 or 2 syringefuls may be injected every 3 hours, or it may also be given internally tolerably freely Of wines I give champagne and of the concentrated alcoholic stimulants I give preference to cognac Too much of a good thing is less harmful than too little in these cases The quantity to be given in 24 hours must be graduated by the indications, and by the results of the first doses

Bed sores may be almost absolutely prevented by a large water mattrass In cases in which they have developed before the use of the water mattrass, they may usually be brought to a stand-still, and generally improved by the mattrass For dressing them boracic acid salve, zinc and lead plaster mulls and white lead plaster should be used Even with the best dressings salves and plasters cannot be held on the sacrum if the patient lies on the back It is therefore best that the patient, even when he uses a water mattrass, should lie on his sides for a few hours each day, but during the height of the fever this cannot be done It is possible during the period of remission, however, and in this stage healing takes place more rapidly But, as a matter of fact, position, antiseptic dressings, etc , are of no value without a water mattrass, though when antipyretic treatment and a water mattrass are used from the beginning of the illness bed sores rarely occur

Such affections of the skin as furuncles, circumscribed gangrene, etc , which are seen in cases of severe typhoid fever which are indifferently treated, rarely or never occur under antipyretic treatment, it is then in the power of the physician to prevent them Baths not only cleanse the skin, but improve its circulation and nutrition, so that the functions of the outer skin, the blood supply of the cutis, and the secretions of the sebaceous glands, are much better than with the indifferent treatment of typhoid fever

In very extensive intestinal affection in the course of typhoid diarrhœa and meteorism are often excessive Faulty diet and frequent use of opium and tannin, and the like, are chiefly responsible for these conditions Do not under-rate the danger of extensive meteorism Aside from the stretching and the irritation of the nerves of the intestinal wall, the secondary effects upon the lungs and heart may cause serious trouble To dissipate this condition one or two ice bladders may be placed on the abdomen, or Priessnitz's pack may be used on the abdomen If this be not sufficient two doses of calomel, of 0 3 each, as recommended by Friedreich, often have the desired effect Naphthalin, and turpentine clysters (a teaspoonful of spirits of turpentine) are also to be recommended[1] Massage of the abdomen has been recommended, but there is danger of its causing perforation of the intestine, especiallly in the hands of a layman

Diarrhœa should, as a rule, not be treated when it is not too frequent, that is, when there are not more than 4 or 5 stools in 24 hours If treatment seem necessary small clysters of opium paste (decoc amyl 30 grams, tinct thebaic gtt xx) may be used The best is the thin clyster made in the house, and injected after the addition of tincture of opium These may be applied, when necessary, once or twice daily, and not only give rest to the intestine, but act well on the general feelings of the patient by dissipating the uneasy sensations in the abdomen

Intestinal hæmorrhage is a very annoying, and prognostically a grave incident, though the mortality in my cases has not been very large in the last 10 years I have lost only 25 per cent of my cases that had intestinal hæmorrhage, while Liebermeister lost 38 6 per cent, and Griesinger lost 31 2 per cent Immediately upon the beginning of intestinal hæmorrhage every kind of food, all medicine, the baths, and every movement of the body are discontinued, and two ice bladders placed over the abdomen Thirst is quenched only with small bits of ice As a styptic a solution of sclerotic acid (1 5, in water) is given subcutaneously, a syringeful every half hour The injection burns, but if properly dissipated by rubbing does not cause an abscess, while the extract secalis cornuti (German Phar , 2d edition) not infrequently does In very profuse hæmorrhage, threatening life, I use enemata of ice-water, the influence of which on the intestinal ulcer is not only of a direct but also of a reflex nature

As regards the use of styptics, such as acetate of lead, which many authors advise (in doses of 0 2 gram hourly at first, then every 2 hours, and later less often, Weil), I have had no experience I have always been afraid of exciting peristaltic action, and on that account have avoided the giving of any and all medicine by the mouth It is possible that I am wrong, however The recommendation of acetate of lead by many authors is certainly not without reason At all events, I recommend that the diet for several days should consist of absolutely nothing, until the immediate danger is past, and there is less fear of a return of the hæmorrhage When the hæmorrhage is very profuse and death from cardiac paralysis is threatened, I would recommend injections of blood or salt water by the method described in a previous lecture A year ago I made a blood injection on account of hæmorrhage in a case of typhoid fever, and with a favorable result

Bleeding during the period of late healing (fourth to sixth week) is more grave as regards prognosis than during the period of casting off the scab (in the second or third week), because it is in this case almost always due to delayed healing of the ulcer and a scorbutic condition of the walls of the ulcer, in which the bleeding is very gradual but lasts a long time It is important to know this, inasmuch as it renders the prognosis much more grave, and calls for very energetic treatment In such cases acetate of lead and other methods come into use

Perforation of the intestine is the gravest accident in typhoid fever The prognosis is almost absolutely fatal Some cases of recovery have been observed, as by Leibermeister Two years ago, in my clinic, there was a case of indisputable perforation, which was sacculated The air which entered the peritoneal sac was withdrawn by means of a trocar, and the sac was healed up, without its being necessary to open the sacculated perforation opening In case of perforation you cannot do better than to give opium *per os* and *per anum* in tolerably large doses continually, as in developing peritonitis the rapid absorption of opium is not very certain, injections of morphia may also be given One or two ice-bladders should be placed over the abdomen, no food whatever

[1] Turpentine given internally in milk or in emulsion seems to do a great deal in the way of counteracting meteorism Bell and more recently Kesteven have called attention to the value of eucalyptol for this condition —[*Trans*]

should be given, thirst should be quenched by small pieces of ice, and every movement of the body should be avoided Should the most favorable termination (sacculation of the perforation) occur, the sacculation should be opened and treated antiseptically, as in a case of perforation of the intestine (of unknown origin) recently reported by E Wagner, which terminated favorably Puncture of the abdomen with a thin trocar to reduce tension in the peritoneal cavity is scarcely ever of more than temporary benefit A curative effect, on account of the generally already existing purulent peritonitis, is scarcely ever to be looked for [3]

The treatment of the most important complications, such as pneumonia, erysipelas, parotitis, otitis, etc , must be regulated by the rules for the treatment of these processes At present we will only speak of the prophylactic treatment, which gives better results than the medicinal These complications have now become very much less frequent under methodical antipyresis It is highly probable that these complications are the results of secondary bacterial invasions Not only is it best to guard against such bacterial invasions by disinfection of the places in which they are likely to lodge, but also against their further growth by cleansing the superficial membranes, removing dried secretions, and cleansing the fissures beneath them The lodgment of Fehleisen's streptococcus in a fissure under the dried crusts of secretions on the alæ of the nose or at the corners of the mouth, in the mucous membrane of the mouth, throat, Eustachian tubes, Steno's duct, and thus the beginning of parotitis, etc , is very probable, and this view is supported by the fact that these complications are only seen in severe cases, and that they may be prevented by careful cleansing and washing of the mouth and nose

The greatest care should therefore be given to the depurative and cosmetic treatment of the mucous membranes of the nose and mouth, in order to prevent fissures and excoriations, wherever it is possible for them to develop In this the value of an experienced and careful nurse is best seen The mouth should be washed daily with luke-warm borated water, the nose syringed with the same, the alæ of the nose and the lips covered with paraffin, boracic acid salve or borated lanolin, and the smallest excoriation brushed with chloride of zinc or sublimate solution, then covered with boracic acid ointment, and with an antiseptic dressing

The care of convalescence from typhoid fever is not the lightest and most thankful task of the physician When the fever ceases patients are anxious to get out of bed, to eat, to walk about, to talk, and receive visits Concede nothing It is better to be too strict than to make concessions that may cause trouble Complete rest of body and mind is essential in convalescence We often see, after too much liberty, and too many visitors, a slight rise of temperature in the evening, a restless night, palpitation of the heart, headache, etc The building up of the muscular system requires several weeks, and any strain, mental or bodily, may cause cardiac acceleration and arythmia, sleeplessness and slight rise of temperature These points are especially important in regard to those who wish to think of or discuss business affairs after an attack of typhoid fever Even after the mildest case the patient should not leave the bed before the fourteenth day, and after a severe attack he should not be allowed to get up before the lapse of three or four weeks The nervous and muscular systems are by this time so strengthened that the patient may soon go into the open air, and the fresh air will then further the return to health more in a few days than would a week in a reclining chair The most necessary visits may be permitted, but they should be limited to 10 minutes

In regard to relapse of typhoid fever The careful physician will be warned of its possibility by the slow regression of the spleen, and will be all the more careful as regards the patient's diet, condition and surroundings While I doubt if a slight error in diet, a visit, or a mental disturbance may be the cause of a relapse, I think that such an error may precipitate it

The treatment of the relapse is about the same as that of the primary attack, but milder Luke-warm and warm baths are sufficient, and antipyretics are either avoided or given in half the ordinary doses In some cases in which the splenic tumor indicated a tendency to a relapse I have given 1 gram of quinine a day for several days In many of these cases the spleen was rapidly reduced in size, but it cannot be proved that the relapse would have occurred had not the quinine been given

In one or two months after convalescence has been fully established, the patient may be sent away from home to the mountains or to a climatic resort, and, when circumstances permit, he should have complete rest for a year

---

[3] It is difficult to imagine why Professor Ziemssen does not even refer to the surgical treatment of perforation of typhoid ulcers—perforative peritonitis The question as to whether already existing peritonitis contraindicates operation has been settled by the successes of Schramm, Boully, Israel, Litten Keith Wells Tait and many others That an operation of this kind on a typhoid patient is a serious matter must be admitted but it has been shown that peritonitis often rapidly subsides after an operation has been made, and the abdomen washed out and drained Three years ago Miculicz reported a successful case of suture of the intestine for perforation by typhoid ulcer The question seems to be so well settled by the successful operations for perforative purulent and other forms of peritonitis that while the time for the discussion of its justifiableness is past it is certainly deserving of mention "It must be submitted as a conclusion from facts and recent experience, that the most *rational treatment of peritonitis is especially of the graver forms*, is by abdominal section" (Stephen Smith Operative Surgery)

In peritonitis from intestinal perforation says Oberst, the diagnosis is surely fair, though he thinks washing out and drainage are favorable only when either there is an encapsulated abscess or no extensive adhesions between loops of intestines have taken place In Miculicz's case a quart of pus was removed, and he sewed up a 6x4 cm perforation in the loop of the ileum The operation was performed 72 hours after the accident Oberst operated in a case of perforation of prolapsed scrotal hernia, 4 days after the accident and when the patient was in a state of collapse The patient's condition was such that suture of the gut did not seem warranted and an anus præternaturalis was made After first 5 days there was no pain or fever But nutrition was difficult, and the patient died of hypostatic pneumonia and decubitus nine weeks after the operation The case is reported in Centralbl f Chir, No 20, 1885

THE BURTON CASE

Read in the Section on Medical Jurisprudence, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY W THORNTON PARKER, M D,

OF NEWPORT, R I

On the morning of October 6, 1885, the quiet town of Newport, R I, was startled by the report that Benjamin J Burton, an industrious and inoffensive colored man, had committed suicide by shooting himself in the head and in the heart The act was supposed to have been committed just after finishing his breakfast The body was discovered lying on its back on the floor near the table where he had been eating The body was stretched out—the head somewhat bent over to the right, the hands natural, the right open, the left not so much so, the legs were slightly separated The revolver was about a foot from the body, the barrel pointed towards it The mouth contained food slightly protruding from it Upon the floor was a teacup tipped over on its side

The Medical Examiner, the Coroner and the City Marshal were soon on the spot The family physician was also present, and among the first to see the body The case was decided as clearly one of suicide, and no inquest was considered necessary It was reported that for some time the deceased had been in poor health and very despondent, and his children testified that he had threatened on more than one occasion to take his own life He dreaded appearing in court, for which he had returned to his house from his office to make preparations It was also stated that Mr Burton had never fully recovered from a severe fall which occurred some months before his death

Considering these facts no suspicion appeared to exist that the deceased had been murdered until after the funeral, when rumors were circulated that a murder instead of a suicide had been committed Finally the community became so excited by increased suspicions that the authorities were obliged to order an inquest The physicians seemed assured that the theory of suicide was satisfactorily proved, and although they deemed an examination unnecessary, the authorities determined to seek further light

At the time of his death Mr Burton's family consisted of his daughter, Maria Dorsey, and her husband, Allen W Dorsey, and a younger daughter, Emily J Burton, a girl of 18 years Mr Burton was a widower His house was a comfortable frame building, with enough room to enable the family to live comfortably and separately Upon the morning of his death the son in law was supposed to be ill in bed The son-in law was a student of medicine at the University of Pennsylvania, and was making the necessary arrangements to complete his studies

Soon after the account of the suicide had been published in the papers I expressed my opinion to the effect that the statements made at the examination concerning the supposed suicide were, in my judgment, impossible The following is the report of the autopsy as communicated to me by the Acting District Attorney "The ball, which entered the cranium on the right side, was found imbedded in the posterior part of the left lobe of the cerebrum, and had therefore traversed the cerebrum from front to back and from right to left

"The brain, being much softened, could not be dissected, and the track of the ball could not be followed, but it was necessarily above the base of the cerebrum, and could not have touched the cerebellum

"Such an injury might have been eventually fatal, and although it might induce immediate loss of consciousness, would not necessarily effect that result

"The other ball penetrated the thorax at a point three inches to the right of the left nipple and two inches to the left of the median line, on a level with the nipple Having opened the chest, its contents were taken out and examined, and it was found that the ball had passed through the left ventricle of the heart, entering near the base and emerging at the apex, which would probably result in instant death Afterward the ball passed between the seventh and eighth ribs, impinging on the eighth rib in a manner likely to deflect it from its direct course The rib was taken out, and the flesh near the point at which the ball passed it was assiduously and minutely explored for an hour or more without success As the ball was very small and the corpulence of the subject excessive, and as the finding of the ball could have no bearing on the object in view, it was concluded to be inexpedient to pursue the search further"

At the first examination Maria Dorsey, the wife, testified that the last she had seen of her father was on the night before October 5, that Mr Burton called them all downstairs and said that he had something very important to say to them He was despondent and said he would not be long with them, he felt badly about leaving the family, especially the younger daughter He said he felt as if he had not long to live, probably not more than a few days at most Mrs Dorsey testified that she saw her father the following morning just before she went into a neighbor's "to fit on a dress," that afterwards she went to the post office, and then went right home again and went into the house by the front door, and thence through the dining-room to the kitchen and saw her father lying on the floor, called her sister and then ran for a neighbor, and then returned She also testified that when she found the dead body of her father, her husband and her sister were upstairs She left her husband sick in bed, and he did not come downstairs until after the discovery of Mr Burton's lifeless body and her own return to the house "We had not been to breakfast at the time of the shooting"—neither her sister nor herself were in the kitchen when the father came to breakfast It was about 9 15 when Maria Dorsey went into Mrs Trager's She was not present when her father's body was taken up from the floor Mr Burton usually ate his meals in the kitchen, did not know whether he had finished his breakfast or not at the time of the shooting, some one led her upstairs after she had

seen her father's body Her husband was studying to be a doctor, but had lived with her father ever since his marriage, although he paid no board either for himself or for his wife Mr Burton did not wish him to do so Her father had never said a word to Mr Dorsey or to herself about remaining at the house, and the best of feelings existed between them all

The younger daughter testified that her father's age was 59, and that he enjoyed good health until the previous summer, when he had a fall He seemed depressed since his fall, seldom said anything about the house Before that he was accustomed to talk freely with them His meals were generally prepared for him and left upon the table for him to eat at his convenience Emily testified that on the morning of Mr Burton's death she had eaten her breakfast alone, Mr Dorsey being sick in bed, and her sister having gone away on an errand As she went to her room she met her sister just starting to go out, she sat in her room reading until startled by her sister's screaming, she then ran downstairs to the kitchen—there was no one there, but her father's body was on the floor She testified also that she saw Mr Dorsey get out of his sick-bed She confirmed the testimony of her sister relating to Mr Burton's depression of spirits and to Mr Dorsey, and also stated that Mr Dorsey seldom met Mr Burton, and that she never knew them to converse together Debts and illness were the only reasons she could assign for the suicide

Allen Dorsey testified that he was 25 years of age, that he had known Mr Burton by sight for several years, and that he had lived with him since the 15th of June, also that he was a student of medicine at the University of Pennsylvania That he last saw Mr Burton six days prior to his death, and next saw him lying dead in the kitchen The screams of his wife first announced to him the death of Mr Burton He was ill in bed, but arose and dressed himself, and rushed downstairs and gave the alarm The reason he did not examine the body when he found it in the kitchen was his anxiety to procure medical help, if possible to save Mr Burton's life He then went upstairs to his room to comfort his wife Dorsey described the position of the body as follows Right arm extended, a pistol near by, barrels pointed towards the body From appearance of the body and the pistol near the hand concluded that Mr Burton had committed suicide Dorsey did not know, he said, until afterwards, where the shots had lodged Dorsey also confirmed his wife's testimony as to Mr Burton's ill-health He affirmed that he had offered to pay Mr Burton board, but that it had been refused He denied that Mr Burton had ever spoken to him in reference to leaving the house He also denied ever having had any trouble with Mr Burton

The Medical Examiner testified that he had known Benj J Burton previous to his death, that he was called on the morning of October 6 to see his dead body Dr Francis had preceded him, and they moved the body from the floor to a table, that together they made an examination, with the results already detailed He further testified that there was not much appearance, if any, of the hair being burned by the head wound, and that the revolver used was so small that it might have been held near the head *without burning* He also thought that the pistol must have been held very near the head for the ball to penetrate as it did

Dr Palmer, of Providence, with the same pistol and cartridges, proved by a series of experiments that the calibre of the pistol was large enough and the cartridges powerful enough to burn the hair beyond any distance which Burton could have held it, and that the positive inference from the unburned hair, which I had stated in the first of the examination, was that the head wound at least was not self inflicted, and that the case was undoubtedly one of murder

But the Examiner justified his theory of suicide by stating that at the time of Mr Burton's death the friends of the deceased were absent, and that Dorsey and his wife said many things which convinced him that the deceased had premeditated suicide This is precisely the attitude taken by the companions of Sergt Rinn (about to be reported), and in my opinion should never be allowed to influence the opinion of the medical officer whose duty it is to carefully examine, weigh the evidence, make the examination, produce the bullets, and report He considered the head wound hardly fatal, and the defense dwelt upon this question of fatality, and made their experts testify to the cases of extensive brain wounds already well known and recorded, in which the fatal termination had taken place only after a long time of comparative comfort

The Medical Examiner stated that there was abundant evidence to prove that a man might live for years with a wound as serious as the wound which he had described He considered that the heart wound was the second one inflicted, and then made the remarkable statement that "the wounds *could have* been *self inflicted, but that this was more possible than probable*" The Medical Examiner exhibited the ball found in the brain, and although it came from a 22 calibre pistol, yet it had been flattened to such a remarkable degree that its passage through the brain must have caused a very considerable degree of damage, tearing and lacerating that structure to a very severe extent, and accomplishing as much harm as a smoother, rounder piece of lead, or bullet from a much larger pistol At the inquest much of the testimony was in contradiction of that given by the children of the deceased, and it was shown that anything but a happy household existed, and that Mr Burton was strongly opposed to his son-in law's living upon his hard-earned money, and that a decided change had been planned by which he should be able to rid himself of his son-in-law and of his daughter's support The testimony also showed that Mrs Dorsey's truthfulness could not be depended upon, and that Dorsey's conduct was certainly open to suspicion

The Newport *Daily News* of Oct 29, 1885, gives the following "Dr W Thornton Parker testified Am a physician of Newport, have heard about the case, have read the description of the wounds, had been an Acting Asst Surgeon in the Army, and have experience in pistol-ball wounds The very positive inference from the fact that the hair was not burned

would be that the wound was not self inflicted It is barely possible that the pistol used in this case could have been held by the person shot Should say the heart wound was the first inflicted *(if suicide and not murder was the cause of death)* If the head wound had been self inflicted and the one first inflicted it would hardly have been *possible* for the heart wound to have been self inflicted (Dr Parker produced a letter from Dr Richardson, of Boston, a surgeon, to the effect that a self inflicted heart wound might be followed by a head wound also self inflicted, but if the head wound were self-inflicted loss of consciousness would follow, rendering a second shot impossible Dr Parker also read a report of a post mortem examination made by him about a year ago, on Sergt Rinn, U S A, at Ft Union, New Mexico, the case being very similar in many respects to the one under consideration) Dr Parker was of the opinion that if the head wound had been the first inflicted loss of consciousness would have followed at once, and the second wound could not have been given immediately The heart wound was, he should say, necessarily and instantly fatal The fact of finding food in the mouth would make the theory of suicide extremely improbable Suicide at the time of eating would seem inconsistent The place of entrance of the shots and the course of the bullets would add to the suspicion caused by the presence of food in the mouth—a suspicion so strong that only a *remarkable exception could account* for the theory of suicide The point of entry of both shots in my view is foreign to the view of suicide The wound in the head directed by a suicide would be more likely to be upward than downward, and the heart wound backward "

During the first examination of Dorsey I wrote to Dr Richardson, of Boston, for his opinion of the case My letter was very brief, and gave only a few reasons for my suspicions I append Dr Richardson's answer, and also a telegram received by me during the examination

SOMERSET CLUB, BOSTON

"*Dear Doctor* — I think with you that the theory of suicide is very improbable It is possible I think for a man to shoot himself through the heart and retain consciousness long enough to make the second attempt, but it seems very improbable indeed If the brain is first injured I believe unconsciousness must ensue and last for quite an interval of time, *after which* of course the second shot may be fired This seems to me quite possible and I have no doubt it has been done by desperate patients I can recall cases in which numerous shots have been fired into different parts of the body, but do not know of any case where the brain has been *perforated* first The man may have used two pistols firing them at the same instant, but this has of course occurred to you I think the matter of burnt hair and clothing very important, as well as the part of the brain injured if the medulla or its neighborhood was lacerated, it would render the firing of a second shot impossible of course If the theory of suicide is to be established it seems to me it must be taken for granted either that the man used two pistols or that he fired the heart shot first, or that he fired the second shot sometime after the first which in that case was the head shot

Very sincerely yours,

M H RICHARDSON

"October 21, 1885 "

The theory of Dr Richardson that a self-inflicted heart wound might be followed by a head wound also self inflicted is correct in a very limited number of heart wounds, and under exceptional circumstances, but in the heart wound of Burton, complete perforation of left ventricle, this theory would not apply, so that looking at the matter from either standpoint the case clearly is one of murder and not suicide So too with the soldier whose post-mortem examination I have recorded *without remarks* As assistant I performed the autopsy, but my Surgeon decided the case to be merely suicide, while to my mind the facts very clearly suggest murder The two severe head wounds occurring so closely together, and the shots occurring so nearly together prove to my satisfaction that Sergt R was shot first in the heart and after falling was then shot by his murderer twice in the head The room was then arranged to suggest suicide, and the mirror was a superfluous addition to the preparations described The following is the record of the autopsy referred to in first examination

"*Record of Post Mortem Examination by Dr W T Parker, 'F A R,' U S Army, Ft Union, New Mexico* From Kansas City, (Mo) *Medical Index*, Aug, 1884 Time of post-mortem 11 30 A M, April 20, 1884, 5½ hours after discovery of the body, and presumably about six hours after death

"*General appearances* Body of a man about 29 years of age, well nourished, healthy appearance Mouth partly opened from which some blood had been flowing Eyelids partly open, particularly right one *Rigor mortis* commencing Upon the head, in the right parietal region, three inches above right ear, are two bullet wounds, one above the other and about an inch apart The hair around the wound is somewhat burnt, bloody and blackened with powder, indicating close contact with the weapon used On the thorax two inches in a straight line to the right of the left nipple is a third bullet wound The under surface of the body is deeply stained (stasis) An incision extending from the right ear upwards across the head dividing the muscles of the scalp discovers two bullets, flattened to a remarkable extent—and imbedded in the soft parts Parts surrounding the wounds on the head slightly swollen and infiltrated with blood The skull is neither broken nor indented

"*Examination of the Thorax* Pericardium distended with semi-coagulated blood The heart weighs 10 ounces A large bullet wound is found completely penetrating the left ventricle obliquely backwards The left lung presents strong pleuritic adhesions At its roots is found the third bullet, slightly scratched by contact with the rib in its passage to the heart. Right lung normal Other viscera not examined

"*Remarks* —The deceased was first seen about 6 o'clock A M, Sunday, April 20, lying on the floor face downwards Near by was a hand mirror not broken,

supposed to have be used by the deceased in the suicidal act A pistol of the British bull-dog pattern, containing three shells, was found close by his left hand About an ounce of blood was found under his mouth which had escaped from the lung His white shirt was blackened in the vicinity of the chest-wound and somewhat stained with blood Two blood-stains from wound in head extended across the face from right angle of mouth The body was slightly warm when found *Rigor mortis* rapidly extending No papers were found on the body In the pockets of the deceased were a few nickels, a handkerchief and twelve pistol cartridges which correspond with those in the pistol which had been fired into the body The body was fully dressed and the doors of the room unlocked"

The case was reported as one of suicide—I am not willing to affirm that it was not a case of murder It was certainly a very suspicious case and should have received a very rigid examination

To aid me in the difficulties of my position as medical expert for the State, and to bring together the opinions of medical men of great experience and of high professional standing, I prepared the following circular and mailed it to many who would be expected to take interest in the medico-legal questions involved

Dear Doctor —I desire to call your attention to the following facts, and to ask your reply to the questions, at your earliest convenience

A middle aged man enjoying good health and owning a comfortable home is found on the floor of his kitchen—dead

He is supposed to have been in the act of eating his breakfast, food is found in and protruding from his mouth, so that at the moment of receiving the fatal shot *he was sitting quietly alone at his own table!* Witnesses declare that two shots followed in rapid succession—first a shot, then a heavy fall, and then a second shot A 22 cal pistol is found on the floor not far from the deceased, presumably placed there by the murderer to carry out the theory of suicide! Upon examination it is discovered that one bullet, probably the first, entered the cranium in the right parietal region, passing through the skull and contents and "was found embedded in the posterior part of the left lobe of the cerebrum and had therefore traversed the cerebrum from front to back and from right to left" The physicians who first examined the body found no evidence of the hair about the wound having been singed to any extent whatever

The second shot "penetrated the thorax at a point three inches to the right of the left nipple, and two inches to the left of the median line, the ball was found to have passed through the left ventricle of the heart, entering at the base and emerging at the apex" The clothing where the bullet perforated it, is burnt, and shows unmistakable evidence of close contact with the pistol when it was fired!

Assuming that this report is correct, is the theory of suicide compatible with the facts?

It is not claimed that the brain wound was necessarily *fatal*, but would not a bullet wound penetrating the skull and traversing the brain cause an amount of unconsciousness, or at least confusion of ideas, for sixty or even one hundred seconds, sufficiently profound to prevent the suicide from immediately recocking the pistol, and discharging it into his heart?

If immediately following the first shot, the man fell heavily to the floor, and *immediately* after that the second shot was heard, does such evidence not prove *murder* instead of suicide?

Could it be possible for a man to shoot himself in the head in the manner described, and then after falling, *immediately* to successfully recock, and aim the pistol and discharge it within two minutes from the reception of the perforating wound of the skull and brain?

Does not the fall clearly prove temporary loss of consciousness?

Considering the facts as stated, is not this very clearly and beyond doubt a *case of murder?*

Very respectfully yours,
W THORNTON PARKER, M D

The following are some of the more important answers received Some replies of value I am not permitted to publish

Surgeon-General F M Gunnell, U S N, writes Your circular letter has been read with interest by the Medical Officers here, who concur in the views formulated by one of them, which I enclose The views of this officer are as follows

1 The pistol *is not found in the hands* of the deceased, but on the floor "not far from the deceased" 2 One bullet—*probably* the first—"no evidence of the hair about the wound having been singed," etc The pistol shot was *fired from a short distance* and *not in close proximity* The track of the wound is "from front to back and from right to left" Now prolong this track in an imaginary line, consider not in close proximity to singe the hair and hold a pistol in the right hand and note the position of hand, wrist, elbow, and shoulder-joint and the position of the pistol in the line stated 3 The fall occurs immediately—there is loss of consciousness and *power of coordinating movements* and this removes the probability of the wound in the thorax being first inflicted The position of the body when found is not given Was he found on either side or on back? for there was a wound

"Penetrated the thorax at a point three inches to the right of the *left nipple* and two inches to the left of the median line, the ball having passed through the left ventricle *entering at the base and emerging at the apex*" Prolong the track of this wound, place the deceased in a prone position and again place the right arm in the position of firing the pistol and note the close proximity of the muzzle to the clothing

From the facts, it is not possible that the wound of the heart was the first inflicted A wound of such character does not permit the element of time taken by the fall, added to the cocking and firing and motion necessary to bring the arm in position to inflict the wound of skull and brain Suicide is not compatible with the facts as stated The fall was from unconsciousness, and it is not possible that there was time for recovery in any degree to recock the pistol, and correlate the movements necessary to inflict the second wound in thorax and heart The track of the wound in the heart precludes any supposition that the movements of recocking, aiming, firing and the positions necessary to inflict such would could have occurred after the wound of skull and brain From the facts as stated the opinion is that the case was *murder*

Dr Thomas G Morton, of Philadelphia, wrote "I presume this is the same case in which I gave a written opinion some months since" He did not consider the theory of suicide compatible with the facts, and in answering all the questions sustained the theory of murder

Dr Bigelow, of Boston, wrote I think the evidence leans so far towards homicide, that the onus lies with those who believe in the suicide theory to prove it

Dr Simon Baruch, of New York, wrote Considering the facts as stated, this is very clearly and beyond doubt a case of murder, but there is better proof in the direction taken by the second bullet (if that is correctly stated) It is utterly impossible for a man to so apply the point of the pistol to his chest as to send a bullet from the barrel towards the apex of the heart And it is highly probable that such a wound was inflicted by some one standing or kneeling behind the victim's left shoulder The theory of suicide is absurd *It may be claimed that by the use of both hands a pistol may be so applied to the chest as to send a ball in the direction claimed,* but even this view would be rendered untenable by actual trial, the adjustment of the pistol would require great precision and steadiness of hand *and considerable time for its execution*

The last statement of Dr Baruch is important when we consider the facts connected with what seems to be the murder instead of suicide of Sergt Rinn, U S Army

Among those sending positive answers in favor of the murder theory were Dr Dolan, of the British *Provincial Medical Journal,* Dr Proctor Thayer, of Cleveland, O , Dr A B Lyman, Baltimore, Md , Dr T D Crothers, Hartford Conn , Dr Chas B Parker, Cleveland, O , Prof F W Draper and Dr M H Richardson, Boston, Mass , Prof T G Morton, Philadelphia, Dr Hunter McGuire, Richmond, Va., Prof W L Davis, Chicago, Ill , Prof Chas B Nancrede and Dr John H Packard, Philadelphia, Dr Henry I Raymond, U S Army, and a few other well known surgeons whose names cannot be made public, some connected with the U S Army, and some resident in New York City

Dr John H Packard, of Philadelphia, besides sustaining the theory of murder, in answering the questions of the circular letter wrote as follows *In regard* to the case stated in your circular received today, I think the existence of two such wounds is conclusive against the idea of suicide The order of the wounds is not so clear The murderer may have fired the first shot from some distance and then advanced and fired again, holding the pistol close to the front of the chest, in which case the victim would probably have been lying on his back when found Or, firing first very close, he may have fired again at the victim's head as he was going away Either of the wounds would, I think, have prevented the self-infliction of the other

Dr D Hayes Agnew, of Philadelphia, wrote If you will read my letter over carefully you will discover I use no such language as you credit me with saying I have never said that the case was one of suicide or of murder, for of that I do not know I have said, and say again, that if the conviction of the prisoner is based entirely on the fact that a man cannot shoot himself in the head and in the heart, or vice versa, with his own hand, he will be unjustly convicted More than this I cannot say until I have heard both sides of the question What little has been communicated to me *differs in several respects* from the statements which you have furnished My informants may be in error, or there may be points which have been withheld from yourself

Many surgeons and physicians in replying stated that suicide was *possible* but not probable, but many more refused to send any reply One well known editor wrote I invariably dodge expert questions, knowing that "things are not always what they seem" In this case they seem very much like a brutal murder, but further deponent sayeth not

With one or two exceptions only, no letters sustaining the suicide theory were received

The following medical gentlemen appeared for the State, and sustained me in every theory advanced in the circular letter already referred to Prof F. W Draper, Boston, Prof M H Richardson, Boston, Dr McClellan, Philadelphia, and Dr Palmer, of Providence Prof H R Storer also sustained throughout the theory of murder, and aided me greatly in the work by encouragement and advice, but declined to appear as expert It was greatly regretted that the services of Dr Fish, of Amherst, Mass , could not have been secured for the State

The objectors must admit that the pistol found, or some other pistol, must have been the means of expelling the fatal bullets Therefore, when the pistol was fired, either by the murderer or the suicide, it must have had a *position somewhere* Then place the pistol where it could send a bullet, without the explosion from the powder burning, singeing or staining the skin, and through the skull bones and brain Could a thick-set, clumsy man, unfamiliar with fire-arms, hold a pistol and fire it in any such position against himself as a suicide must have held it? Certainly he could not Then consider the other shot, first or second, as one may choose, this entered the left ventricle and passed through the heart, emerging at the apex Could such a man as already described hold the pistol to do this?

The writer is familiar with most of the cases brought forward by the defence to prove how tolerant the brain is of severe injury, notably "the case of the iron bar," as it has been termed, and which is so well known to the students of the Harvard school, and to most of those who will read this paper As stated in my circular, "It is not claimed that the brain wound was necessarily *fatal,* but would not a bullet wound penetrating the skull and traversing the brain cause an amount of unconsciousness, or at least confusion of ideas, for sixty or even one hundred seconds, sufficiently profound to prevent the suicide from immediately recocking the pistol and discharging it into his heart?" This a large number of prominent surgeons have answered in the affirmative

The question of the ability of a 22-calibre cartridge, when exploded, to burn hair, is settled in the affirmative by the very careful and complete experiments of Dr Palmer, of Providence, who used the same cartridges as found in the revolver, and the identical revolver supposed to have been used in the murder In every experiment he proved beyond a doubt that it was absolutely impossible for Burton to have held the pistol and inflicted the wounds without at the same time burning the hair and staining the surrounding tissue This fact alone must have *proved* beyond doubt the theory of murder as

the only one tenable in view of these conditions, as conclusively testified to by the medical examiner and other competent medical witnesses This absence of burned hair or staining was one of the first facts obtained by me in determining that it was a case of murder

The records of the Surgeon-General's office and the experience of surgeons prove beyond a doubt that the usual result of a severe penetrating bullet-wound of the head is a certain amount of immediate unconsciousness, evidenced usually by a fall The remarkable exceptions are not to be used as evidence to support the theory of suicide As Prof Bigelow has stated, the *burden* of proof rests with the advocates of the suicide theory It is for them to prove suicide The State should not be put on trial to defend a position so reasonable, but *the defense must prove* that the reception of a penetrating bullet-wound of the skull and contents is not necessarily followed by unconsciousness The overwhelming evidence of the past fifty years of surgical history demonstrates to the unbiased observer that Mr Burton could not have inflicted upon himself the wounds which destroyed his life Such evidence cannot be gainsaid or resisted, and how it can be answered differently it is hard for me to understand

In the case of Sergt Rinn two shots were fired at the head, entering the scalp within two inches of each other Is it probable that a suicide would select two places so near together? The bullets which struck Sergt Rinn's head were large and came from a powerful British bull-dog pistol These bullets must have struck the head with terrific violence, since when discovered by the knife at the post-mortem they were found to be flattened to a remarkable extent Is it reasonable to suppose that after two such staggering blows this man could shoot himself in the heart? Was not the placing of the hand mirror a mere subterfuge to suggest suicide and hide the murderer?

It was claimed by the defense that suicides very commonly select the head as a target for the suicidal shot However much truth there may be in this statement, it must be equally true that when such a wound is inflicted powder stains or burning must necessarily follow, but the main objection to the argument in connection with the Burton case is, that *immediately* after accomplishing this penetrating pistol-ball wound of the brain the supposed suicide was able to accurately place, hold in position and discharge for the second time the pistol sending the ball into the heart This is, in all human reason, an impossibility, and not *one case* can be brought forward to illustrate this extraordinary theory The defense asks us to believe too much, forgetting that the burden of proof rests with them and *not* with the State But when within a few moments of the murder it was discovered by at least one competent surgeon that no burning of the hair or staining of the flesh had taken place, and at the same time, if a case of *suicide*, the pistol was obtainable for inspection, then the suspicion of murder should have increased to such an extent as to lead to the immediate decision of a premeditated homicide, and should have demanded immediate action by the police authorities

The question of the amount of *time* after the receipt of a wound in the brain, before unconsciousness would ensue, has provoked very much discussion It seems to me that in ninety-nine cases in a hundred there is more or less immediate shock, varying all the way from slight bewilderment and loss of reasoning to absolute loss of sense This is one of the most important questions connected with the case, and the plea of "possibility" is the plea only of *possible exception*, which in point of fact only proves the rule.

Considering the facts as stated, is not this very clearly and beyond doubt theoretically a *case of murder?* Practically it terminated as follows Maria Dorsey, the elder daughter, completely broke down upon the evening following the expert testimony for the State To a friend she said that the testimony of the five medical experts was more than she could endure, and so gave up a full confession The senior counsel abandoned the case, the jury soon brought in a verdict of guilty for both Maria and her husband, Allen W Dorsey, and they were promptly sentenced to State's Prison for life, the extreme penalty in Rhode Island To complete the case, Dorsey himself confessed his awful crime, and so the famous case ended

A CASE OF EPILEPSY APPARENTLY CURED BY CORRECTION OF HYPERMETROPIA AND RELIEF OF CILIARY SPASMS

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY G E FROTHINGHAM, M D,

PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY OF MICHIGAN

I am led to report the following case not for the purpose of advocating any theory, but by a sense of duty to record a fact that may add to the statistical data to which appeal must be made in settling the question as to how important a part, eye-strain plays in the etiology of nervous affections This subject has been a mooted one for several years, by some condemned as of little importance, but by its originators and supporters pressed as one of the most important factors in the production of various nervous diseases, even as frequent cause in the production and maintenance of epilepsy and insanity, the most exalted manifestations of nervous disturbance, and the least curable by medication Believing, with Hoffman, that there is no escape from the labyrinth of doubt created by controversy, except by carefully and diligently consulting the records of cases, I have concluded to contribute this mite to the great whole by which we can only settle this question As it has been now more than three years since the last manifestation of disease, we may claim that the cure is permanent, whether or not it is due to the means that apparently effected it or not The following is a brief account of the case

An April 22, 1884, I was consulted by Miss E J L , aged 24, daughter of Rev V L L , then residing in Ann Arbor, Mich She came to consult me con-

cerning epileptic spasms with which she was afflicted, and also about some visual disturbances that had always given her trouble Her father, who accompanied her, gave the following history of the case She was an unusually healthy child until her eleventh year, when she was very suddenly attacked with a convulsion lasting about five minutes, after which she lay in a deep sleep for between one and two hours, from which she awoke apparently all right The family physician thought the attack due to intestinal worms, and gave some remedies based upon this view In about a month another spasm of the same kind occurred, and for sometime thereafter, they occurred monthly, or varying not more than one or two days from that period This regularity in occurrence led the physician to believe that possibly it was a case of premature menses, and that some obstructions to the escape of the discharge caused the irritation that produced the spasms, which were all of an epileptic character The limbs were drawn up, head bent backward, the teeth firmly set, the tongue often bitten, until, after awhile, the premonitory symptoms being recognized, a cork was inserted between the teeth and the injury to the tongue thus prevented There was frothing at the mouth and general convulsive movements The spasms were not preceded by an outcry, but in every instance there was, just before the convulsions, dizziness, color seeing and flickering before the eyes If these symptoms continued more than a few minutes a spasm occurred These symptoms occasionally appeared for a minute or so at a time without being followed by the epileptic spasms, but they always preceded the spasms, and a persistent attack of this kind was the means by which the patient was able to foretell a convulsion

When the patient was about twelve years of age Dr Lewis A Sayre, of New York, was consulted He examined the patient carefully, and concluded, that the spasms were due to some gastric derangement, or to some pre-catamenial derangement of the nervous system, and that they would probably disappear after a sufficient lapse of time Bromide of potassium was prescribed and, after awhile, Brown-Séquard's method of treatment was adopted and faithfully carried out The spasms could be controlled for a time, but, in a few months would return as before, and all remedies became ineffectual After the brief respites afforded by remedies, the convulsions would recur with more violence than before The bromides of potassium and sodiums were used until the nervous system became much depressed and the health and strength greatly impaired The patient was not only weak and languid, but became greatly reduced in flesh

When fourteen years of age Dr Wm A Hammond was consulted, and after a critical examination, including an ophthalmoscopic examination, concluded that the trouble was due to congestion, or other disease, of the base of the brain He gave an unfavorable prognosis, but recommended the use of nitrate of silver, which the parents objected to and it was never given

From the age of fifteen to eighteen, the patient was under the care of Dr A L Turner, of Bloomsburg, Pa, who was able, by his remedies, to keep the spasms off longer than had been accomplished by any previous method, but did not effect a cure, while the bromides used by him, as a part of his treatment caused much depression and enfeeblement She next came under the care of Dr E I Dunster, of Ann Arbor, Mich, who omitted, for awhile, the depressing medicines and gave tonics The spasms were even less frequent than before but still continued up to the time she consulted me, April 24, 1884 She was at that time spare and anæmic, with an anxious troubled expression of the countenance, and had the appearance of being older than she really was The menses were regular and the convulsions seemed to have no connection with this function There were occasional headaches, and symptoms of asthenopia, though not very severe An examination of the eyes showed the vision of each eye normal ($\frac{20}{20}$) and manifest hypermetropia varying from 0 50 to 0 75 D in both eyes alike There was no insufficiency of either the external or internal recti, or any abnormal relation existing between the external muscles that could be detected An ophthalmoscopic examination showed a normal condition of each fundus, but a total H much greater than shown by the subjective test The patient accepted a + 1 50 D S for each eye in reading, and experienced a feeling of relief and comfort in using them

April 26, the accommodation was paralyzed and a total hypermetropia of 2 D was found to exist in each eye The corresponding glasses were prescribed, the atropine continued, with directions to omit it after two weeks, and after another two weeks to gradually resume the use of the eyes by Dyer's method The period of rest was, however, inadequate, for on June 9 the patient returned and I found the manifest hypermetropia varying between 0 75 D and 2 D, which latter was the total amount There had been no return of the epileptic convulsions since the first examination, and the patient was feeling some better I directed a more prolonged use of the atropia, reduced the strength of the glasses to + 1 50 D and directed a return to the use of atropia whenever these should blur distant vision I also gave the usual directions for easy use of eyes

I did not see the patient again as she went East, and I did not hear anything more of the case until Nov 26, 1886, when the father wrote me from Bloomfield, N J, his present home, as follows "I am prompted to write you a few lines about our daughter Emily, which I thought might be of some interest to you professionally You will recall that for years she was troubled with spasms, preceded by color seeing, flickerings and dizziness We tried many physicians both East and West, among them were Dr Lewis A Sayre, and Dr Wm A Hammond, of New York The relief was only partial and temporary, meantime by the use of bromide of potassium, and like sedatives and antispasmodics, she was constantly feeble Dr Dunster prescribed for her as well as yourself, but you said that some claimed that these troubles originated in, or were continued and aggravated by certain abnormal conditions of

the eyes, and you made an examination and advised the immediate and constant use of glasses, and a discontinuance of the bromides of potassium, sodium, etc Well, before we left Ann Arbor, a marked improvement was observed—strength returned, she gained in flesh, and was in every way better, and now, during some two and a half years, she has never had a spasm, the color seeing is *very* seldom, and she is so fleshy and well you would hardly know her She has taken no medicine in two years Now I am inclined to think the glasses were the remedy, and I thought it might confirm your judgment in such cases, and be gratifying professionally, to know the result"

On Feb 12, 1887, in answer to some inquiries, I heard from this patient, and the improvement had still continued as at the date of the letter above quoted Considering this lapse of time, we are justified in regarding this case as apparently cured, and from the history it would seem that the cure was effected by the correction of an existing hypermetropia I have not been investigating in this direction, and had it not been for the thoughtfulness of the father of this patient I should never have known the result

It is several years since the attention of the profession was called to the connection which some claimed to exist between errors of refraction and nervous diseases, such as chorea, epilepsy, etc The views promulgated by some of the early writers on the subject were generally rejected as extreme, and this has been my own view in regard to them The possibility that they may have been *too lightly* estimated, is sufficient excuse for continued agitation of the subject, and for the collection of *every* fact that may tend to aid in its investigation and settlement

On March 1 of the present year Dr Geo T Stevens read, before the New York Neurological Society, a paper entitled "Irritation Arising from the Visual Apparatus Considered as Elements in the Genesis of Neuroses" He reported a series of most remarkable cases, in which the correction of slight errors of refraction, or the relief of insufficiency of some of the recti muscles, had caused immediate improvement in patients demented by epilepsy, which had resulted, as he believed, from the eye strain He cites cases of insane patients at the Willard Asylum, who were considered incurable, that were apparently benefited by this method of treatment Fourteen patients were treated by him Ten of these were insane and demented epileptics These patients were found to be suffering from insufficiency of one or the other of the recti muscles, and were operated on by him for its relief During the month preceding the operations these patients, collectively, had 170 convulsions During the month following the operations these patients, collectively, had only about 40 attacks, and this, notwithstanding the withholding of bromides Such facts should at least command attention, and did receive due consideration by the distinguished gentlemen present None of those who participated in the discussion, except one, could cite personal experience corresponding with that quoted by the author of the paper, and many were inclined to combat the extreme views advocated therein All agreed, however, that a complete examination of the eyes, including their refraction and the condition of the external muscles, should be made in all nervous affections

Dr Stevens declared in his paper that, as a result of an analysis of over 5,000 cases of nervous diseases occurring in his private practice, besides a considerable number in public institutions, he had come to the conclusion that "difficulties attending the function of accommodation, and of adjusting the eyes in the act of vision, or irritation arising from the nerves involved in these processes, are among the most prolific sources of nervous disturbances, and, more frequently than other conditions, constitute a neuropathic tendency" Granting that his experience is exceptional, and his views extreme, may there not be more in this theory than is generally believed, even by oculists Neurotic patients generally come under the care of those who give their attention to general practice, or who confine their practice to nervous diseases, and by them the condition of refraction and the relation of the external muscles are often too lightly investigated By many it seems to be ignored, and the paper of Dr Stevens, above referred to, has been characterized editorially in a leading journal as a "narrow specialism," and not long since, when a case was reported in one of the medical societies of some nervous disease cured by properly fitted spectacles, the editor of the journal containing the report volunteered the remark that "no well educated physician of the present day would make such a claim"

Peripheral irritation, as from tapeworm, etc, has long been recognized as a cause of epilepsy, but it has generally been held that when the *status epilepticus* has once become established by any of these peripheral causes, the removal of the cause does not cure the malady Numerous cases can, however, be found in modern medical literature that tend to discredit this view Epilepsy has been observed to disappear after the removal of various sources of eccentric irritation, such as the removal of a diseased knee joint,[1] the relief of preputial irritation,[2] the restoration of a prolapsed rectum,[3] the restoration of a retroverted uterus,[4] the removal of carious teeth,[5] and by the enucleation of a diseased eye[6] We can hardly consider these cures of epilepsy, which had existed for ten years in some of these cases, as the mere result of the traumatism inflicted by the operative procedure, as was suggested by Dr Seguin in discussing Dr Stevens's paper,[7] but it must be regarded as due to the removal of a source of eccentric irritation, which in some cases is the exciting cause of the epileptic spasms This peripheral irritation may exist in any part of the body, but we can readily conceive that excitement, strain or irritation

[1] Med and Surg Reporter 1883, No 48 p 26

in *some parts* may more readily produce these derangements than excitement or irritation in some other portions of the body, just as excitement or irritation of the parts supplied by the glosso pharyngeal nerve more readily excites the vomiting centre than irritation in other parts, though several portions of the body seem quite intimately connected with this centre Has the eye a similar connection with the coordinating and motor centres? and is eye strain, as claimed by some, "among the most prolific sources of nervous disturbance, and, more frequently than other conditions, constitute a neuropathic tendency?"[8] This is a question worthy of investigation and answer

Dr Chas A Oliver recently published an analysis of the ocular symptoms obtainable in epilepsy in the male adult [9] He based his conclusions upon the examinations of fifty male adults, of American stock, inmates of the State Hospital for Insane at Norristown, Pennsylvania All were epileptics In his ninth conclusion he says "The presence of insufficiency of the interni in the majority of cases is readily explained by association with existing H + Ah, and probably has no relation with the epileptic condition " In the light of the report made by Dr Wise, of the Willard Asylum, to Dr Stevens, as to the apparent benefit following his operations in similar cases, are we prepared to accept Dr Oliver's conclusion, above quoted, without further investigation?

Ferrier, in the second edition of his great work on "The Functions of the Brain," issued last year, discards his former view, which located the visual centre in the angular gyrus, and he now locates it in the occipito-angular region He declares that, though the cerebellum is not essential to sight, it has intimate relation not only with the optic, but also with the oculo-motor nerves, as is shown by the importance of visual impressions on the mechanism of equilibration, and by the relation between oculo motor and general motor adjustments, demonstrated by experiments The superior cerebellar peduncle is suggested as the probable medium of communication of optical impressions with the centres of equilibration [10]

The hope that the report of the above case might excite some discussion, and lead to the relation of experience and expression of the views entertained on this subject by the members of the Society, is the excuse for its presentation here

---

CONSERVATIVE DENTISTRY

Read in the Section on Dental and Oral Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY A E BALDWIN, M D , D D S ,
OF CHICAGO, ILL

I have chosen for the subject of my brief paper " Conservative" or " Preservative Dentistry," and my only apology for presenting such a paper as this, is the hope that it may draw out some discussion, and do something toward clearing the minds of many general practitioners of medicine from fallacies, inherent from a lack of a proper appreciation of this subject and a prejudice which many of them must have obtained from the constant rantings and railings about the lamentable ignorance of the Doctor of Medicine, by some of the would-be lights of the dental specialty I will be excused in the light of the above in making this paper deal largely in generalities, thinking by thus doing that the mind of the general practitioner may enlarge upon these generalities, and through them we may hope to enlighten the laity, who are, as a rule, willing to do anything which their physician recommends or which they can believe is for their good, especially in regard to their physical condition

I think I am not stating it in too strong language when I say, that if there is one factor more than another that brings the people to the physician it is the troubles arising from indigestion It assumes a variety of forms, and is almost always largely owing to the condition of the teeth

This matter is fully as important in the child as in the adult (and to my mind much more so) Take the child, for instance, from four to twelve years of age, growing rapidly, the amount of nutrition furnished must be largely in excess of that necessary (in proportion to size) for the adult, for they have not only to assimilate a sufficient quantity to make up for the waste, but also for the great development and growth in, and of the tissues How often do we see the child with decayed teeth, nearly or quite exposed or dead pulps, and these unattended to, makes him very careful of masticating food the consequence is the food is imperfectly commingled with the saliva, and goes into the stomach in a solid instead of a pulverized condition, the stomach is overworked, the system is underfed, and these things tend to develop a nervous, hypersensative condition of the organisms of the body, and especially of the nervous system, and we see them illy nourished, thin, nervous and weak, and with that worst of all habits formed for life, of never using the teeth save to get the food in a condition to be swallowed And then oftentimes when the child's tooth gives him a little trouble, the parent takes him to the family physician who extracts the abused tooth and thus paves the way for irregularities of the permanent teeth, instead of explaining what is necessary, *i e*, to take him to the family dentist and have the tooth or teeth put in good repair, to require at least semi annual visits that they may be kept in such a condition that mastication can be performed painlessly, and the space occupied by the temporary teeth maintained until the eruption of the permanent tooth to take its place—for should it be extracted, it is a well known fact that the remaining teeth tend to close the space occupied by the tooth, and thus the permanent tooth must be erupted in an abnormal position Should the above be carefully followed, I think much of the decay and suffering from the teeth later in life would be obviated, and the system kept better nourished, the stomach not overworked and the general condition much improved

[8] Geo T Stevens M D N Y Med Jour April 16 1887 p 422
[9] See Philadelphia Med Times February 5, 1887 p 306
[10] Ophthalmic Review, April 1887 p 124

And what I hold to be true of children is in a large sense true of adults, and I know there are many general practitioners who are as thoughtless of the outcome, in the matter of the teeth, as I was when in the general practice, often then extracting or advising the extraction of a tooth when by so doing I was doing the patient an incalculable amount of harm While I do not mean to be understood as advocating the doing away of the forceps entirely, yet I think a rule might be formulated something like this—"No tooth or good root of a tooth should ever be extracted if it is in a position where if sound, it would be serviceable" Of course, this is not an invariable rule but the exceptions would hardly be noticeable

Many of you may recall the acrimonious discussion in and out of the *Medical Record* of a short time ago in regard to leaving in the mouth of pulpless teeth, especially after an abscess had formed at the root But I think a quiet examination of the subject will develop the fact that if the inside of the tooth, *i e* the pulp chamber and the canals, are thoroughly desiccated and then filled with an indestructible and non-irritating material that the tooth remains as inoffensive to the tissues near to and far removed as though it were perfect as nature formed it

Oftentimes, in medicine as in other things, guess work or tradition compels innocent things to be pronounced guilty, and I think the cases are very rare where trouble in other tissues may be traced even indirectly to a well treated pulpless tooth I know I am taking grounds that may be criticised by some, but when reflected upon I think they will be very generally accepted

Now, in regard to the tooth and the surrounding tissues, or connections with other organs These connections are of nerve tissue and the circulation by which the pathological condition can be communicated, and in the devitalized or pulpless tooth the troubles are caused, as I suppose, by the putrefaction of the confined tissues with the formation of irritative gaseous products, and these being compelled to escape, must escape at the apical foramen of the root, and this causes irritation of the peridental membrane and inflammation, exudation and suppuration following from what is known as an abscessed tooth Many physicians and, I am sorry to say, very many dentists too, here think the proper treatment is to extract, but I, in common with most of the dental specialists, hold as according to the teaching of Prof Allen, of Rush Medical College "Having found what was the matter and the cause, remove the cause,"—not the tooth, for that was not the cause, the cause being the irritation induced by the confined gases, give these gases an opportunity to escape by freely opening into the pulp chamber, remove as thoroughly as possible the putrefying débris, dry or dessicate the pulp chamber and root canals I think, as a rule, disinfection is not necessary, as the thorough drying is a perfect disinfection, and then having accomplished this, to fill the root canals with a material that is of itself non-irritating and not affected by any of the fluids of the system, and the material *par excellence* is a thick solution of base-plate gutta-percha dissolved in chloroform This, pumped into the root canals and forced to the apical foramina, entirely removes the cause for any further irritation Many dentists, I know, claim this can be accomplished better by other means, but I am confident the majority of cases of failure of this treatment is in not having the canals thoroughly dried, and as this material shrinks in drying, if the walls are not thoroughly dried, the shrinkage is *from* the walls, allows infiltration of fluids into the canals, and an undesirable result follows

I am willing to affirm, that a tooth with canals *thoroughly* dried and filled with the solution of gutta-percha in chloroform will never again give trouble from irritation, save from some external condition of tooth which, may or may not exist entirely independent of the fact as to whether the tooth has a living or dead pulp

And to illustrate the external causes which may act, I mention a case that came to me some eighteen months ago, with the request to examine a tooth which had troubled him for years and had been treated by some of the most skilful dentists in the West with no relief After a careful examination I told him I could do nothing of benefit to him save to extract the tooth In spite of the much-vaunted ability of some men to relieve all such cases, I think this was clearly a case where relief could only be obtained by the removal of the tooth, a lower left first molar The anterior root being entirely encrusted with a thick deposit of tartar, this extended all about the root, clear over the apical foramen of the root and up between the roots to the top of the arch, and partially down the other root on the inside Now, why was not this condition recognized and treated properly a long time before, at a great saving of time and money to the patient? I can conceive of only one reason, and that was, the mind of the dentist was so bent on demonstrating a theory that the interest of the patient was not thought of

Some of us are so taken up with seeking myths from and in materia medica that they are imposing many ridiculous things on us, giving us more chaff than wheat, forgetting that first a thorough, unbiased examination and clear demonstration of its value, should precede the foisting of it upon the profession, and while for a few years, perhaps, we should be denied the infliction of so many voluminous papers of trash on dental materia medica, yet progress would be safer and more sure And another prominent dentist is constantly pressing on the profession theories, many of which have been exploded years ago by the medical profession as of no value, and nearly (if not quite) all are simply theories, with no clear demonstration of the facts as applied to our work I think the greatest of the faults in the dental ranks is that we do not do enough original thinking, we are too apt to let one doctor or another do the thinking for us, and do not depend enough upon ourselves—if we did we should not be so ready to receive and embrace false doctrines As it is now, if any question comes up, the mass of the profession first want to learn what Dr So-and-So thinks, not stopping to con his reasons (if he has any) for his ideas, and at once adopts them as his own

As an illustration of the way we should do, I have only to refer to the story of the young artist who, meeting the old and celebrated artist, inquired of him how he mixed his paints to produce the harmonious blending of colors in his pictures, and was astonished at the (clear) reply of the artist "I mix them with brains" Could we get this little truth established in our minds, and ere we do anything, use our brains as to the cause and the remedy, we should soon be more in a condition of scientific progress and have many less theories

It is much easier for us to see faults in our brother, the general practitioner, than to see the much greater faults in ourselves, and if we can get the general practitioner to simply apply the same rules in his reasonings in regard to the dental tissues as in those that he is oftener called to treat, and to recognize that the abscessed or pulpless tooth is *not* a dead tooth at all, but simply one that by proper treatment can be made a good and serviceable instrument for mastication, the writer of this paper will be gratified beyond measure

MEDICAL PROGRESS.

Metrorrhagia at the Time of Puberty —In an article on this subject Dr Henry C Coe says

As regards the treatment, I can only add that it should be largely expectant, since the hæmorrhage tends to cease spontaneously Absolute rest in the recumbent posture, with the avoidance of all disturbing influences, is generally sufficient The patient ought not to be allowed to get out of bed for the purpose of emptying the bladder or bowel, neither should be permitted to become distended, since this tends to increase the hæmorrhage On the other hand, violent purgation is equally to be avoided, since it augments the pelvic congestion

As regards drugs, the fluid extract of *Hydrastis canadensis* has been highly recommended in uterine hæmorrhage, but it did not seem to act so well in this case as ergot I have not met with such good results from the use of aromatic sulphuric acid as others Since the hæmorrhage in these cases is an expression of the general pelvic congestion, it is a question if, by endeavoring to promote uterine contractions, and hence local anæmia, we do increase the existing hyperæmia in the pelvic vessels The conditions in the case of a virgin and in that of a multiparous uterus are manifestly different

As regards the application of cold to the abdomen, as recommended by German writers, it is to be noted that this agent should not be employed indiscriminately I should not have ventured to use it in this instance if I had not been sure that the hæmorrhage was not the true menstrual flow Even then the ice-bag was left *in situ* for only half an hour at a time Its use in such a young patient during the period might be productive of harm, by modifying unnaturally the normal hyperæmic condition of the pelvic organs, just as sometimes occurs in consequence of a cold bath at that time

Vaginal injections are always extremely distasteful to a young girl, and, in consequence of the anatomical condition of the parts, they cannot be given thoroughly If employed at all, they should be administered slowly, and should be non irritating The amount of water and the force of the stream must necessarily be smaller than would be used in the case of a multipara A simple astringent, such as alum, is preferable It is a question if they accomplished much good in the case described, they were, at least, not productive of harm

To summarize Metrorrhagia at the time of puberty is not necessarily pathological, and rarely calls for local treatment If dysmenorrhœa is absent, if no general cause can be discovered, and the patient is not profoundly affected by the loss of blood, the chances are that the condition is temporary, and that it will cease when she is placed under proper hygienic conditions, which conditions can only be determined by experiment Treatment should be mainly expectant, while vaginal examinations are rarely necessary —*N Y Medical Journal*, August 27, 1887

The Cerebro-Spinal Fluid —Falkenheim and Naunyn agree with Bergmann in regarding the cerebro spinal liquid as a true secretion from the plexus choroidens and not a simple transudation The normal subarachnoidal pressure is from 7 5 to 12 mm of mercury in a strong dog The amount of fluid secreted varies much in different dogs, from 1 ccm in 6 minutes to 1 in 40 minutes The secretion is not dependent on the blood pressure nor on the size of the animal, although the resorption of the fluid is An increase in the pressure of the cerebro-spinal fluid may result from an increase of the arterial or venous blood pressure, since the resorption of the fluid cannot compensate for the effect of raised blood pressure

The authors believe that under circumstances of disease an increase of subarachnoidal pressure leads to symptoms of pressure on the brain only through anæmia of the brain, is the result only of overcoming the usual blood pressure in the brain-vessels They believe that symptoms of such pressure arise only under very peculiar circumstances when due to an increased secretion of fluid, but that they arise readily from disturbance of resorption The pressure necessary to produce symptoms is not a constant one, but depends upon the pressure within the vessels of the brain —*Centralbl fur klin Med*, No 33, 1887

Nitroglycerine in Nephritis and Uræmia — Dr S A Lentovsky, of the Cronstadt Marine Hospital, employed nitroglycerine (in tabloids containing each 1-100th of a grain of the drug) and hot water baths in four cases, three of which are given with minute details In two of the patients the daily amount of urine rapidly increased, while albuminuria and dropsy disappeared and the patient's subjective feeling and general state strikingly improved In a third case the improvement was but fleeting, the patient dying after a short stay at the hospital The

And what I hold to be true of children is in a large sense true of adults, and I know there are many general practitioners who are as thoughtless of the outcome, in the matter of the teeth, as I was when in the general practice, often then extracting or advising the extraction of a tooth when by so doing I was doing the patient an incalculable amount of harm While I do not mean to be understood as advocating the doing away of the forceps entirely, yet I think a rule might be formulated something like this—" No tooth or good root of a tooth should ever be extracted if it is in a position where if sound, it would be serviceable " Of course, this is not an invariable rule but the exceptions would hardly be noticeable

Many of you may recall the acrimonious discussion in and out of the *Medical Record* of a short time ago in regard to leaving in the mouth of pulpless teeth, especially after an abscess had formed at the root But I think a quiet examination of the subject will develop the fact that if the inside of the tooth, *i e* the pulp chamber and the canals, are thoroughly desiccated and then filled with an indestructible and non-irritating material that the tooth remains as inoffensive to the tissues near to and far removed as though it were perfect as nature formed it

Oftentimes, in medicine as in other things, guess work or tradition compels innocent things to be pronounced guilty, and I think the cases are very rare where trouble in other tissues may be traced even indirectly to a well treated pulpless tooth I know I am taking grounds that may be criticised by some, but when reflected upon I think they will be very generally accepted

Now, in regard to the tooth and the surrounding tissues, or connections with other organs These connections are of nerve tissue and the circulation by which the pathological condition can be communicated, and in the devitalized or pulpless tooth the troubles are caused, as I suppose, by the putrefaction of the confined tissues with the formation of irritative gaseous products, and these being compelled to escape, must escape at the apical foramen of the root, and this causes irritation of the peridental membrane and inflammation, exudation and suppuration following from what is known as an abscessed tooth Many physicians and, I am sorry to say, very many dentists too, here think the proper treatment is to extract, but I, in common with most of the dental specialists, hold as according to the teaching of Prof Allen, of Rush Medical College "Having found what was the matter and the cause, remove the cause,"—not the tooth, for that was not the cause, the cause being the irritation induced by the confined gases, give these gases an opportunity to escape by freely opening into the pulp chamber, remove as thoroughly as possible the putrefying débris, dry or dessicate the pulp chamber and root canals I think, as a rule, disinfection is not necessary, as the thorough drying is a perfect disinfection, and then having accomplished this, to fill the root canals with a material that is of itself non-irritating and not affected by any of the fluids of the system, and the material *par excellence* is a thick solution of base-plate gutta-percha dissolved in chloroform This, pumped into the root canals and forced to the apical foramina, entirely removes the cause for any further irritation Many dentists, I know, claim this can be accomplished better by other means, but I am confident the majority of cases of failure of this treatment is in not having the canals thoroughly dried, and as this material shrinks in drying, if the walls are not thoroughly dried, the shrinkage is *from* the walls, allows infiltration of fluids into the canals, and an undesirable result follows

NITROGLYCERINE IN NEPHRITIS AND URÆMIA — DR S A LENTOVSKY, of the Cronstadt Marine Hospital, employed nitroglycerine (in tabloids containing each 1-100th of a grain of the drug) and hot water baths in four cases, three of which are given with minute details In two of the patients the daily amount of urine rapidly increased, while albuminuria and dropsy disappeared and the patient's subjective feeling and general state strikingly improved In a third case the improvement was but fleeting, the patient dying after a short stay at the hospital The

Hewitt says "I am aware of the disorganized condition of the department when you entered upon your duties, and I am convinced that you have done all in your power to bring order out of chaos Before the close of the present year I hope to be able to inform the people of New York that every tenement which is unsuited for healthy occupation of its citizens has been vacated I congratulate you on what you have done in this direction since you have been in office, but I cannot refrain from urging you to use all the means at your command to remedy the grievances which have been complained of and close up any house in this city which is not fit for human habitation "

Regulations in regard to plumbing and ventilation have also been adopted, and under these there is to be an entire abolition of what is known as the "school sink" in tenement houses, and the substitution therefor of water closets Provision has also been made for the use of extra heavy cast iron pipe in all cases, and the use of tarred iron pipe will not be allowed All closets must be connected with the outer air Among the other evidences of new vigor in the administration of the Health Department is the prosecution of a number of physicians for neglecting to report births and cases of contagious disease occurring in their practice

PATHOGENIC MICROORGANISMS IN SPUTA

In some investigations on this subject, the full records of which are published in the *Zeitschrift fur Hygiene,* Bd 2, 1887, D BIONDI took sputa from 50 persons, some in health, others ill, and injected it into animals When pathogenic results followed the tissues were searched for microorganisms, and these cultivated and isolated In this way he found 5 different kinds of microorganisms Of these the *Bacillus salivarius septicus* was found in 20 per cent of the sputa examined, and it was most abundant in the sputa secreted before mid day Dogs and mice into which 5–1 cc of such sputum was injected died in the course of 24 to 72 hours Before death there was usually fever, sometimes also continuous coma In some cases death did not take place till after the lapse of 30 days, the animals gradually emaciating, and the hair falling, etc After death œdema and hæmorrhage were found about the point of infection, as well as in the parenchymatous organs and serous cavities The spleen was swollen, and the microorganisms were found in the blood

Biondi made a careful examination into the biology of these bacilli They are short, elliptical rods, somewhat pointed at the ends He found that if the infected blood was used as a means of inoculating from animal to animal it was strongly pathogenic On the contrary, if the bacilli that had been grown on artificial culture media were used the pathogenic power diminished with the age of the culture It was also found that if the bacilli grown in artificial media were used as a vaccine material animals were protected from the more pathogenic material

Another form—the *Coccus salivarius septicus*—was found in the sputa of a patient who had puerperal septicæmia Mice, guinea pigs and dogs inoculated with it died in from 4 to 6 days The blood contained the cocci isolated or in small groups In the tissues they were found constantly in thick nest-like collections They did not cause purulent inflammation They grew rapidly on agar agar, gelatin, blood serum and bouillon, and did not render them fluid On potatoes and milk they grew poorly, and developed best at the temperature of the blood They also developed at a temperature of 18°–20° C

A third form—the *Micrococcus tetragones*—was found three times Animals infected with it died in from 4 to 8 days The most pronounced symptoms were great weakness and feebleness These cocci were found in unusual numbers in the blood and secretions, and in greatest numbers in the lungs They grow on all the usual culture media, and at the usual temperatures They are pathogenic to mice and guinea pigs, but not to dogs or rabbits The pathogenic activity of the cultures was not altered by their age

The *Streptococcus septo-pyæmicus*—the fourth form—was found three times in the sputa of persons who were ill (angina phlegmonosa, laryngitis, erysipelas) The sputa were pathogenic, but not constantly, in guinea pigs, mice and dogs The dogs generally died of a form of chronic septicæmia, and the guinea pigs and mice of a collection of pus found at the point of infection, which had a tendency to spread through the subcutaneous tissues and muscles This coccus grows on agar agar, bouillon, and potato It appears to be identical with the coccus of erysipelas, and of phlegmonous and puerperal sepsis

The fifth form—the *Staphylococcus salivarius pyogenes*—was found in an abscess produced by injecting beneath the skin of an animal sputa from a patient suffering from scarlatina anginosa Besides this, abscesses often developed at the point of injection, which contained staphylococci identical with the *aureus* and *albus* The *S salivarius pyogenes* differs from these in that it renders culture media fluid more slowly On agar agar the culture appears

whitish gold yellow, the *aureus* being deep red and the *albus* snow white On gelatin it frequently forms a membrane, which is not the case with the others It is very resistant to both high and low temperatures

THE OBSTETRICAL ADVANTAGES OF OTTER TAIL CO, MINNESOTA —Otter Tail, one of the frontier counties of Minnesota, bids fair to rival the Rotunda Hospital or the Allgemeine Krankenhaus of Vienna as a resort for aspirants for obstetrical advantages and greatness Dr T G Hutton, of Fergus Falls, writes us that there are now in that county living quadruplets one week old, living triplets eight months old, living twins born of a 16-year old mother, and a child 12 months old whose mother is now only 14½ years old It may be added, for the benefit of those who may hesitate between Vienna and Otter Tail Co, that the latter place is just as accessible as Vienna, and the cost of living is less The only reasonable objection to the frontier county is that the vernacular is English, nevertheless, it contains, we believe, a large number of Germans

SOCIETY PROCEEDINGS

ST LOUIS MEDICAL SOCIETY

Stated Meeting, April 30, 1887

THE PRESIDENT, S POLLAK, M D IN THE CHAIR

DR MEISENBACH presented a specimen from a

STRANGULATED OMENTAL HERNIA

The patient was a middle aged man On January 16 Dr Wesseler saw him suffering with a strangulated hernia, which he reduced The man had had hernia for the last seven or eight years—hernia of the left inguinal region After the reduction he neglected to wear his truss Five days after the first strangulation of the gut, while lifting, the intestine came out and became incarcerated Dr Wesseler attempted to reduce the hernia by taxis, failed, sent for me, and I failed to reduce it Under taxis the tumor became flaccid, and as the more urgent symptoms had been ameliorated, it was decided to wait till morning and see what development would occur During the night the patient's condition again became worse, the tenseness of the tumor increased, and vomiting occurred An immediate operation was advised The tumor was very tense, and there appeared to be some exudation, as on palpation there was marked resistance and that evidence of doughiness which is very difficult to describe, but which is very perceptible to the sense of touch The man was anæsthetized, the usual incision made over the tumor and an attempt made to reduce it without opening the sac When I thought I had reached the gut I found that I had only cut down to the sac, because upon making a very minute puncture, after trying in vain to reduce the hernia without opening the sac, I found there was an exudation of about three quarters of a pint of serum Even then it was impossible to reduce the tumor Upon opening the sac I found a coil of intestine within it, and an immense mass of omental tissue I finally succeeded in replacing the gut within the abdominal cavity The gut seemed to be still living, and in a condition which seemed to promise that it would live Its color was a deep cherry or wine color I returned it to the abdominal cavity, as there were no evidences of gangrene in any portion But when I came to the omental tissue I found that there was such an extensive coil, with strong adhesions present, that it was impossible to return it I attempted ligation and the dissecting off a portion of the tumor, but such hæmorrhage ensued that I desisted, being afraid to dissect off the adhesions to the walls of the ring for the same reason I could not get at the underlying tissues effectually enough to control the hæmorrhage that might occur, and I was afraid to cut off the omentum that was protruding and leave a stump that would probably cause the same danger, hæmorrhage into the abdominal cavity I concluded to leave the omental tissue within the sac or extruded from the sac, and suture the sac to the neck of the omental protrusion The patient for the first 24 hours seemed to be doing fairly well, but within 48 hours he died, I think from shock, because upon the autopsy we found the abdominal cavity free from serous and hæmorrhagic exudation, but that portion of the gut which had been entangled in the sac for over 12 hours was black, it had not broken down, there were no points of puncture, of rupture or signs of extravasation, but there was this first stage of gangrene I found all the parts surrounding the internal and external abdominal ring and in the line of the operation in good condition, there was no infiltration

If the operation had been performed six, eight or ten hours earlier could the man's life have been saved? Did the protrusion or the leaving of the omental tissues in the situation in which we left them have anything to do with the hastening of the collapse of the patient?

DR F J LUTZ mentioned a case of omental hernia in which he pursued a different course from that taken by Dr Meisenbach, the indications being different It was an umbilical hernia in a woman 35 or 40 years of age, who received an injury, some eight years ago, by falling on the ground and striking a piece of wood on her abdomen She was a very large woman, weighing about 200 pounds She then noticed a protrusion which gradually became larger and gave her much pain, the size and pain increasing There appeared to be no question as to the nature of it The feel of the tumor indicated that the bowel was not included There were certain symptoms, however, which had latterly appeared and which indicated that there was considerable traction upon the stomach, the mass of omentum in the tumor was so great, that whenever any kind of fluid

or even liquids which could develop gases in the stomach were introduced there was such an amount of traction and pain as to make the patient's condition unbearable The supposition was that possibly latterly a portion of the bowel or stomach had got into the sac No truss or appliance has ever reduced the tumor I opened the sac and at once came upon a mass of omentum, which appeared very much like a fatty tumor, so that when we have made an incision into them there were a number of fibrous bands extending and forming, as it were, separate cavities, which cavities were filled with the omental mass The sac appeared about the size of a man's fist, and yet probably three times as much omentum as would be represented by a man's fist was in the sac, so firmly and densely was it packed, and after unraveling the omentum it was seen to escape from an opening perhaps three-fourths of an inch in diameter, that it had been greatly enlarged and thickened, and was firmly adherent to the surrounding structures, so that it had to be dissected off On finding that the contents of the sac was omentum, the first suggestion was that this omentum should be reduced into the abdomen, and I succeeded at first in introducing a part of it, but afterwards I did not succeed in getting it into the abdomen Then the question of enlarging the opening through which the tumor escaped, was presented The objection was that I had not put my hand or any instrument into the abdominal cavity because I had checked the hæmorrhage at this period, nothing had been done to the sac except make an incision in the median line If I enlarged the opening I possibly could not succeed in keeping all the blood out, and as it would undoubtedly be necessary to manipulate, the contents of the bowel might escape also Then it seemed that if this woman had got on for so long a time without that omentum in her abdomen, because it was only latterly that any disturbance had occurred, possibly she would get along just as well afterward without it, I therefore, after reducing some of it, or as much as I thought would relieve the tension on the stomach, proceeded to ligate the mass with strong silk ligatures in three or four places, and cut off the remaining portion of the omentum The stumps were then readily reduced I then began to sew up the opening in the abdominal cavity by means of four interrupted sutures, which, however, only approximated the parts, and after that I removed the sac, leaving a ring of peritoneum outside the abdominal cavity, in other words, not cutting the sac off very close to the sutures, I left half an inch, and dressed the cavity, which was left after introducing a drain of sublimated gauze The patient is getting on very well

DR E H GREGORY said it had always been his rule to strangulate the omentum and cut it off just beyond the ligature and leave the remaining portion in the ring, not disturbing it at all, leaving it there in the hope that it may serve as a plug, or a sort of internal truss He never disturbs the adhesions of the omentum at all, but simply strangulates it, being very careful to unravel it, because occasionally when we think we have reduced the bowel completely we find nestling in the meshes of this omentum yet remaining a knuckle of intestine, and it requires a great deal of caution lest we might embrace a portion of the bowel in the ligature, so that it has been his rule to unravel the omentum as perfectly as possible, then ligate it, using three or four ligatures occasionally, but usually simply a double ligature, which enables me to embrace it in two loops, and then cut it off In a case like this I should certainly have recommended an excavated truss—a pad that was sufficiently capacious to have received this mass, and a resisting pad, one that would have prevented any increase of the tumor, and I should have hoped from the pressure of this pad, persistently used, to reduce the size of the mass, I should have hoped for this result, I have seen it happen, and I attach as much importance to the good results of an excavated pad as I do to the ordinary pad for keeping up a hernia If a pad be properly constructed, if it fit closely to the mass, it certainly prevents any additional protrusion of the mass No one who has an irreducible hernia ought to do anything which is likely to produce a protrusion, if he has a stricture it ought to be cured, because every effort at discharging the urine is apt to produce a fatal protrusion But I believe that circumspection under these circumstances, and properly fitting excavated pads, make these hernias almost as safe as ordinary hernias which are kept up

In regard to the intestine We have some rules in surgery One rule is that if there is a doubt in our minds as to the propriety of performing a surgical operation, we should give the patient the benefit of the doubt by not performing the operation Hernia forms an exception to this rule Where we have a protruding mass with urgent symptoms, or symptoms which suggest the propriety of surgical operation, the best way is to operate—to give the patient the benefit of the doubt by performing the operation, because the operation gives him a better chance than procrastination, so that when I have a case of hernia, if there is a doubt in my mind as to the propriety of an operation, I always operate That is my rule When I open the hernial sac and find the intestine changed, but intact, if I am in doubt as to the propriety of returning it, I put it back, if I am not, I leave it out, that is, if I am satisfied I should not return it I leave it out, because I am satisfied from the condition of the gut that it would be perilous in the highest degree to put it back, it is dead, and I certainly leave it out I cut it open and empty the contents of the intestine But whenever I am in doubt to put it back or not, I put it back, because it is then in the best possible situation to be restored—to have its vitality restored If left out, it will most probably die, if put back we will always hope that it will grow better, because then the intestine is at home An earlier operation in Dr Meisenbach's case would have been infinitely better, and must be infinitely better in every case of strangulated hernia to operate at once The question is, is a hernia strangulated? is it simply incarcerated? is the transit of its contents simply arrested, or is its circulation interfered with? Whenever there

is strangulation, the circulation of the part is arrested, the term includes the idea of a vital interference with the circulation, and whenever there is a strangulation, relief must be afforded as quickly as possible There being strangulation, there is no ground for the surgeon to stand on I always say to a patient before I give him the anæsthetic, I am going to give you an anæsthetic and put you upon the table, and when you wake up you may find that I have operated, because if I fail to reduce the bowel, I shall make an opening which will enable me to relieve this constriction I often succeed in reducing, but always have this sort of an understanding Generally the symptoms of strangulation are very distinct, unequivocal, of course there are exceptions, strange and mysterious as it may appear, a bowel may be fatally nipped without urgent symptoms, but as a rule there are urgent symptoms, and there can be no question about the propriety of an immediate action

Dr D V Dean said that Dr Meisenbach's case brought up one point that is likely to be the subject of some discussion in the near future, the matter of resection One of the younger surgeons of this city is preparing a paper in which he cites a considerable number of cases in which strangulation or incarceration existed quite a brief period of time and herniotomy was performed, and, death following, a post-mortem examination showed minute punctures or openings in the line of constriction of the bowel He asked me to look up my cases, and I found an account of a case in which an operation had been performed, and, in the report of the autopsy it was stated that minute openings were found In all my later practice, if the tumor do not reduce readily, I give an anæsthetic, and then if it do not reduce, perform an operation But this question of resection is one that is important to consider Of course it would not have saved the patient's life in Dr Meisenbach's case at the time he operated, for he died of shock I expected to hear that there were openings at the line of the constriction, and I was almost sorry this condition was not found But, if the patient had not died of the shock, he would have died from the results of gangrene of the bowel

Dr T F Prewitt thought the great mistake that is made in nine cases out of ten of strangulated hernia is that the operation is not performed early enough It is always safer to operate early with or without antiseptics It was before we had antiseptics, it is so now The danger to the patient of not operating is in proportion to the damage done the bowel I venture to say that in 99 cases out of a 100, if they are operated on even needlessly, and the operation was done properly and skilfully, the patients would do better than if they were let alone The operation is not a dangerous one itself It is the condition of the bowel which imperils the life of the patient There are two or three points in Dr Meisenbach's case that interested me In regard to the condition of the bowel, I think it was Mr Keyes, one of England's most conservative surgeons, who said that under all circumstances the best place for the bowel is in the belly He did not mean by that that it should apply to the case of a sphacelated bowel, that such a bowel should be pushed into the belly, but that it should be the rule that in cases of doubt, the bowel should be returned to the neck of the sac, it should always be done if there is the slightest doubt about its being dead, that is the proper thing to do, even if it is dead you cannot do any harm by it, for the very reason that if the bowel is dead, nature is there to protect it, she throws a protecting wall around inside by the localized peritonitis which has taken place in the abdominal cavity, and unless the surgeon ruthlessly thrusts his finger up and breaks up the adhesions, the abdominal cavity is thoroughly protected, and if he presses the bowel down to the neck of the sac and leaves it there, even though it is absolutely dead no harm will result The statement of Mr Keyes did not apply to any such procedure, it simply implied that it should be pressed back to the neck of the sac and left there If it was dead an opening of the bowel would take place spontaneously and an artificial anus established by nature's methods In all cases in which there has been acute strangulated hernia, and the bowel is in bad condition, it is never prudent to thrust the bowel into the peritoneal cavity, it should simply be pressed into the opening and left there, and if its vitality is not fatally damaged it will be all right In a case of recent protruding omentum, where strangulation takes place, whether the bowel empties or not it ought to be returned without an operation All hernias ought to be returned without operation unless there is good reason to believe there is serious damage to the contents of the sac, this is the only condition which makes it prudent, advisable or good surgery to open the sac, unless the conditions are such that it will not go back into the sac Then of course it is absolutely necessary to open the sac

In the old cases of hernia, where the omentum has protruded a long time, it invariably thickens up and looks like a mass of fat rather than omentum, its character is entirely changed We may be able to unravel it, as Dr Gregory says, but I believe that whenever, in an old hernia, the omentum has undergone this sort of change, as it will inevitably, sooner or later, if it be protruded, especially if the patient is in the habit of wearing a truss—I believe in all such cases where a strangulation takes place, and when the bowel becomes strangulated, it does not matter whether we can reduce the bowel or not, I believe it is infinitely better for the patient that we cut off the omentum, and I think the patient is in a vastly better condition than if it is left, because if we leave it, the patient will suffer some time or another with strangulated hernia, whereas if we cut off the omentum we furnish the best condition for a permanent cure Destroy the sac if you choose, dissect off the entire sac, and leave the pedicle as a plug in the outlet I believe this is better practice Most certainly it is advisable in every case of strangulated hernia upon which we have to operate, where the bowel cannot be reduced, and it is necessary to open the sac I believe the best practice in those cases is to ligate the mass of omentum and cut it off, not, however, without first searching in the omental sac for a knuckle of intestine, where it is very apt to lie

concealed Some years ago a patient came to me with a large scrotal hernia and desired to have it operated upon I opened the sac and succeeded in getting the bowel back, but there were three pounds of omentum which I cut off, tied it, left a pedicle in the opening, and he got well, not without a bad symptom, though, because he had a good deal of trouble, an inflammation set up in the scrotum, there was a good deal of sloughing, etc I used antiseptics, but probably imperfectly In another case of an old woman that I operated upon, I cut off quite a mass of omentum, and the result in this case was good Dr Lutz, in speaking of the case of omental hernia, said he did not understand what good a concave truss would do, that it could not push the mass back That is true, but the object of the surgeon is not to push it back, but it is to prevent the further protrusion that we use this truss If that woman had worn a concave truss when the hernial mass was one-half the size it finally attained, she would not have had the disagreeable symptoms—the dragging sensation I think Dr Lutz acted wisely in cutting it off I think it would be bad to push it back into the abdominal cavity It is like a foreign body when it is so pushed back It has lost the character of omentum, it would be an irritant, and I believe it is bad practice to push it back when it is possible to do it It is better to tie it and cut it off

DR MEISENBACH said it occurred to him that the correct procedure would be to cut off the omental mass, leaving the stump to plug the abdominal ring, but he could not carry out his original intention on account of the hæmorrhage He does not think, however, that there was any chance for the bowel to get out again If he had not found that the patient died from shock, he would have thought that possibly if the omentum had been cut off and returned, it might have given the patient a better chance

DR T F PREWITT presented a case of

POPLITEAL ANEURISM

This man is 31 years of age now When a boy something like 14 years of age he received an injury in the popliteal space from a file which his brother threw at him There was a little hæmorrhage at the time, there was perhaps a little swelling, but he tells me he was going about after a little while without difficulty, and it gave him no trouble for years In 1878 he had an attack of sunstroke, and some little time after the sunstroke, a month perhaps, while sitting at the table looking out of the window, he felt a peculiar sensation in the popliteal region and a general weakness, and putting his hand down he felt the pulsations of a swelling in the popliteal space He says the leg swelled a great deal and that the pulsation was very marked, more so than it has been since that time He called his mother's attention to the tumor, and she put her ear to it, and could hear the bruit very distinctly, like water rushing through, as she expressed it Then a physician was called in, who recognized that it was an aneurism, and asked the late Dr Hodgen to see it He saw it and was very much interested in it, and advised that he wear an elastic stocking The patient did this, wearing out two pairs I first saw the patient some two or three years ago, when he was suffering from alcoholism, and he called my attention to the aneurism I recognized it as an arterio-venous aneurism I was undecided whether there was a well defined sac or not, it was a very soft swelling, very easily compressible, and it seemed to me more like a dilated sac than like a varicose aneurism An interesting feature about it is that, as I have stated, the injury from which the trouble started occurred twelve or fourteen years previous to the symptoms of aneurism appearing This form of aneurism is almost always the result of injury, not always, because they are sometimes actually congenital, but I think Mr Bryant states that of 57 cases of aneurism of this character perhaps 32 or 33 were traumatic A very large proportion were traumatic, and we generally expect to find them occurring from some traumatic origin Another rather peculiar fact is that when I saw the case it did not strike me that it was likely to give him much trouble, it was not a very large pulsating tumor, and as it is the rule in surgery to let them alone unless there is some good reason for interfering, I paid but little attention to it Subsequently, however, he went out and fell into the hands of another physician, who operated, and as I understand tied the artery above the point of communication I learned from him that this never seemed to stop the pulsations, or never completely did so Whether or not the sac was laid open at the time of the operation I do not know At all events I understand the artery was tied above the communication He came back to me recently with the tumor considerably enlarged Before I knew what had been done I examined the case, and satisfied myself that it had not been tied below, because if we make pressure above it does not stop the pulsation, but if you make pressure below you can control it He tells me that after the operation he was in bed for five months, and that after getting up he had to go about on crutches for two months The tumor is undoubtedly fed by the return current Tying the artery above cuts off the direct current I will tie it below

---

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, April 20, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR L L FRIEDRICH read a paper entitled

ENDOSCOPY

As is generally conceded the endoscope is an instrument that is very little used by the profession at large, and to some its use and appearance are very vague, and, in fact, unknown The busy practitioner has no time to use it, and hence only a few specialists are in the habit of employing it either as a means of research, or, more properly speaking, as an aid in diagnosis and treatment in obstinate diseases of the urethra and bladder The older and more complicated instruments of Desormeaux,

Cruise, and their various modifications, are no better than a simple straight urethral tube, blackened on the inner surface and furnished with an obturator They may be either metal or hard rubber The latter are to be preferred for caustics These instruments are made of various sizes, from No 18 to No 26, Charière scale

To make a thorough examination the tube, having been well oiled and warmed, is introduced gently into the membranous urethra, the obturator withdrawn, the oil and mucus wiped away from the presenting membrane at the bottom of the tube by means of a little cotton twisted on a long double-ended probe The illumination is then brought to bear directly upon each portion of the membrane inspected as the tube is withdrawn The ordinary laryngoscopic reflector answers every purpose With a little practice it is not difficult to distinguish healthy from diseased tissue But, as with the ophthalmoscope, at first all seems red The healthy mucous membrane has a pale, pink color, and contrasts strongly with congested spots, which are of a vinous red without polish Such spots can be plainly seen as they come across the end of the tube Any granulations are readily recognized by the practiced eye, and local applications of considerable strength made which could not be applied with safety by any other means Great care is to be exercised that the cotton on the end of the probe is firmly attached, and the patient at the same time warned not to move or violently withdraw the tube so as to leave the cotton with the caustic either within the bladder or posterior urethra The topical remedy for granulations suggested by Desormeaux, and which can be very accurately applied, is a solution of nitrate of silver 3ij to the ℥j (8 to 32) up to a saturated solution The latter should only be used in case of large granulations, and then only very lightly Iodine, sulphate of copper, tannin, etc , are also used, and give fair results, especially copper sulphate 33 per cent The great advantages of this method of treatment are, that the spot to which an application has been made may be inspected from time to time and the effect of treatment be critically observed This treatment is to be repeated at first several times a week, then weekly until the cure is established Success is sure to attend the prolonged intelligent use of the endoscope But it is only the most obstinate cases, which have withstood other treatment, that require the prolonged applications

The occurrence of urethral chancre is not very uncommon It is my fortune at present to have under treatment a case, which the endoscope served to detect, that several eminent gentlemen had been treating for gonorrhœa There was no lumpiness around the urethra, no painful spot on erection, no bloody discharge from the urethra, yet upon a careful examination I detected upon the roof of the urethra, about one inch from the meatus, the chancre, a slight oval sore whence the discharge emanated This is undoubtedly a urethral chancre, for gonorrhœa does not produce an ulceration of the urethral mucous membrane No doubt the creamy discharge, with the pain on micturition, led to the mistake in this case, as is likely where only a superficial or hasty diagnosis is made When last seen the patient had the enlarged inguinal glands, and the other symptoms of the constitutional disease, namely, roseola syphilitica, etc

A similar case has been reported of a patient who was treated for gonorrhœa, his symptoms being those of a creamy discharge and pain on urination After awhile constitutional symptoms were developed, and the endoscope introduced long after showed a faint cicatrix at the point of the old ulcer on the upper surface of the canal

Prof von Dittel showed that by means of the endoscope and electric light the interior of the bladder could be thoroughly examined Prof Ultzman uses the endoscopic tube with brush attachment, without aid of reflected light He claims that by this means he can do just as well, and as the other procedure takes too much time for his extensive practice, he prefers it Grunfeld gives a great variety of diagrams and plates for the different portions of the urethra, which he claims are characteristic for each Polipi, epithelial growths, etc , are readily seen Prof Janowisky, of Prague, says that the endoscope is sometimes valuable in prognosis, and as an aid in diagnosis, especially in the strictures of wide calibre, as described by Otis

Dr Yarrow said that he had tried to use the endoscope but had never been successful, probably from lack of skill

Dr Friedrich found difficulty in using it at first, but after seeing it in the hands of the masters he had learned to use it successfully He found that one must work quickly and must wipe away all the mucus and oil before a good view can be obtained, even then the field soon becomes dimmed

Dr D S Lamb reported a case of

DEATH FROM ILLUMINATING GAS

Dr R D DeL French, who was called to the case, writes me as follows Lucy K , mulatto, age about 18, retired between 10 and 11 P M , March 31, 1887, having first blown out the gas which was turned on full Nothing more was heard of her until her employer rapped at her door without receiving any reply after 6 A M , April 1st The room being forcibly entered, she was found asphyxiated, the gas having been escaping into the room from the time when she blew it out Her body was cold and rigid lying partly on the right side with her tongue out and her mouth full of and covered with froth She was almost pulseless and her respirations slow and shallow Pupils completely contracted and her skin and lips pale She had vomited (some remaining in her mouth), and had evacuated the contents of her bowels The window had been opened and the doors and other windows allowing the gas to escape A good stiff breeze was blowing into the room through the open window I had the patient placed in front of the window immediately, her limbs swathed in sinapisms and hot poultices applied to her thorax Ordered 5 grains carb ammon every half hour and whiskey *ad lib* Applied electricity, one electrode to cervix and the other to præcordial region This

DR G WYTHE COOK had a case of a child of 12 whose mother had put it to bed and had unwittingly turned the old fashioned gas key too far, so that though the light was extinguished the gas continued to escape The child was found unconscious and breathing stertorously, he was very pale, and had vomited When seen by him the only symptoms were pallor and headache Recovery

DR G N ACKER related an unpleasant experience from inhaling coal gas from a stove He had retired about 12, and when he regained consciousness he found himself upon the floor attended by a physician and several other people He was told that he had awakened the people of the house by the loud noises which he made about 3 A M He felt stupid for a day after this, and for several days he had a buzzing in his ears and felt very much indisposed He is now very susceptible to coal gas, which causes flushing of his face and an uncomfortable feeling generally

DR C L MAGRUDER mentioned transfusion as another method of treatment Transfusion of blood, milk and saline solutions have been successfully employed in cases of this kind, even several days after the accident

DR LAMB stated that in the references which he had looked up transfusion was not regarded as being of much value

FOREIGN CORRESPONDENCE

ST GALL AND ZURICH[1]

Tuberculosis of Cranium—Prolapse of Uterus—Sonderegger—Ambuhl—Zurich — Kronlein — Swiss Universities—Resection of Chest Wall and Lung—Osteomyelitis of Fractured Bones—Infectious Strumitis—Struma Operations—Carcinomatous Stricture of Colon—Klebs—Rohrer

After visiting Lindau, Bregenz and Rorschach, I arrived in St Gall May 4 This ancient city is the capital of the Canton of the same name, and although it has only a population of 30,000, it has two excellent hospitals, the Kantonspital and the Buergerspital, the latter, however, is only intended for convalescents, incurables, and serves at the same time as a poor house Each of the hospitals contains about 100 beds Dr Hilly, a physician of excellent local reputation, has charge of the medical wards, Dr Feurer of the surgical, and Dr Kuhn of the gynecological Both Dr Feurer and Dr Kuhn are young, energetic men and excellent operators, and besides their onerous duties in the hospital do a large and lucrative private practice I saw a number of interesting operations, and satisfied myself that excellent scientific and practical work is done here The antiseptic treatment is thoroughly carried out and the operating room is supplied with all modern improvements and with an excellent assortment of instruments

I saw here an interesting case of tuberculosis of the cranium in a woman about 30 years of age, where repeated operations had been performed, and over a large area corresponding to the superior longitudinal sinus the entire thickness of the bone had been removed, but the disease returned a short time after every operation, and at present a number of sinuses lead to tubercular depots The disease evidently creeps along the structure of the diploe, and is extending very rapidly By continuity it has also extended to the dura mater, where it has given rise to a tubercular pachymeningitis, as the patient suffers from periodical attacks of headache and vomiting In the children's ward I was shown a child several months of age with a meningocele the size of an adult's head As the case is undoubtedly complicated by an encephalocele, no operative measures have been instituted

Dr Kuhn performed on the same patient and at the same time three distinct operations for an aggravated prolapse of the uterus As the cervix was very much enlarged, a wedge shaped piece was excised from both lips in such a manner that a complete cone was removed and the hæmorrhage arrested by carefully suturing with catgut The cystocele was corrected by excision of an oblong piece of mucous membrane of the anterior vaginal wall, and the parts again sutured with catgut The last operation was the customary colpo-perineorrhaphy During the excision of the flap of mucous membrane the incisions were carried so deep that the rectum was exposed for some distance, and a number of vessels which bled freely had to be ligated Catgut was used even for suturing the perineum The German surgeons almost without exception use the knife instead of scissors in vivifying the parts in all vaginal operations, and it certainly seems to me that the wounds thus made are in a better condition to heal by rapid union than in cases where the tissues are cut with scissors In this case at least a tablespoonful of iodoform was deposited in the vagina with a spatula, and the vaginal outlet was covered with a compress of iodoform gauze As a disinfectant, both in the surgical and gynecological wards, a solution of corrosive sublimate 1–1,000 is used, and sublimated gauze and cotton as a dressing

For years I have been aware of the fact that St Gall was the home of the leader of the medical profession of Switzerland, and I was therefore exceedingly anxious to become personally acquainted with Dr Sonderegger I never met with a more cordial reception, and his good wife insisted on serving a genuine Swiss dinner, and the doctor supplied the table with a brand of wine such as can only grow in the most favored valley in Switzerland, a Velthner almost as old as the doctor himself Dr Sondereg ger is the author of one of the best books on sanitary matters He has a national reputation as an orator, and enjoys the respect and friendship of all who know him With word and action he is always eager to preserve the honor and dignity of the medical profession and to impress his colleagues and the Government with the importance of preventive medicine To his untiring efforts is due the establishment of a small laboratory in the city, where Dr

[1] By permission of Drs Fenger and Senn

Ambuhl, an able chemist, has done excellent service in improving the hygienic condition of the city and surrounding country towns I am convinced that such an institution, with such a man at its head, is a greater benefit to a community than our more expensive local Boards of Health

After spending a few days in my native village in the beautiful valley of the Rhine, I came to Zurich, and remained in this place a whole week The hospital is the same as when I was here nine years ago, but a walk through the surgical wards was enough to show me that a change of directorship had taken place When I was here before I saw the sad results of the open wound treatment as advocated and practised by Rose in every ward and almost in every bed The rooms were filled with unpleasant odors from decomposing wound products, wounds were suppurating, and the patients looked haggard and many marasmic Primary union was not aimed at, and consequently was never observed Since then Kronlein has taken Rose's place, and the whole aspect of things has undergone a radical change The open wound treatment has given way to careful antiseptic measures, and in the same rooms you can hardly find a febrile patient In the great majority of cases wounds heal by primary union, and suppuration is an exceedingly rare occurrence Professor Kronlein is hardly 40 years of age, with a strong constitution and unlimited capacity for work He first came into prominence by his controversy with Volkmann, and it is generally conceded that after a harsh and bitter fight he came out victorious He next became well known as Langenbeck's favorite assistant, and during his term of service he wrote several articles which have since been frequently referred to by most authors and teachers Switzerland is now to be congratulated that the chair of surgery in all universities is now occupied by distinguished Swiss surgeons For centuries it had been customary to import young men from Germany as professors, who remained until they received a call from some German university, when they resigned to make room for another one of their countrymen There was no earthly reason why the Swiss universities should have remained so long as training schools for the German Privat-Docenters, and it is to be hoped that after this, when a vacancy occurs, home talent will at least be given the first chance

The surgical wards in the hospital contain eighty beds, which are always occupied Zurich has 270 medical students of which number forty are females The female students here, as in the other schools in Switzerland, do not sit together in the operating-room, but prefer to mix thoroughly with the sterner sex A look at the female aspirants for the medical degree is enough to show of what metal they are made In the female wards I saw the young lady whose case has been mentioned by almost every medical journal in the world, as Kronlein had removed a part of the chest wall and a portion of the lung for sarcoma She recovered and remained in good health for more than a year, when a return of the disease was observed in the cicatrix A few weeks ago the third operation was performed, when another piece of the lung was removed with a still larger section of the chest wall The wound is now entirely healed, and the patient left the hospital the same day, in excellent health The last operation was followed by an attack of croupous pneumonia

From a pathological standpoint another case attracted my interest A young man sustained several subcutaneous fractures from a fall, and at the same time a lacerated wound of the groin The case progressed favorably until the wound commenced to suppurate, when he was suddenly attacked by osteomyelitis of the fractured bones, which necessitated numerous incisions for the liberation of pus at the seat of fractures There can be no question that in this case the pus microbes entered the circulation at the primary seat of suppuration and were arrested at the seat of fracture, where they found favorable conditions for growth and initiated a suppurative inflammation in the medullary tissue Practically this case should teach us that in a patient who has sustained a simple fracture it is exceedingly important to guard against suppuration in any part of the body, for fear that from such purulent depot germs might enter the circulation and cause a suppurative osteomyelitis of the fractured bone, in the same manner as has been done by experiments on animals

A case of strumitis with a somewhat similar origin also attracted my interest The patient was a man about 40 years of age who had been operated upon for empyema by rib resection some time ago He had a large goitre since childhood The case progressed very favorably until the empyema was nearly well, when suddenly the temperature rose and the right side of the struma became painful and tender After a week fluctuation was well marked and a large incision was made, which gave exit to a large quantity of fetid pus The fever subsided at once and the case again progressed favorably until, a week or two later, the opposite side of the struma was attacked in a similar manner I was present when this side was incised A large amount of the same fetid green pus escaped The strumitis was undoubtedly of embolic origin, the germs which gained access into the circulation from the pleural cavity found in the struma conditions which favored their localization and development, and produced a suppurative inflammation

Of the numerous operations I saw during the week I will only detail two cases of struma operations In both cases the operations were performed to relieve distressing symptoms Chloroform narcosis was only kept up until the tumor was fully exposed, after this it was considered dangerous to continue its administration for fear that it might produce asphyxia

The first case was a boy 20 years of age who had the commencement of a goitre ten years ago The tumor gradually increased in size until recently it has given rise to a great deal of difficulty in breathing Externally the tumor is not prominent, but when the head is thrown backward it can be distinctly seen to dip down behind the sternum He has also experienced some trouble in swallowing, and its presence seems to have kept up a constant irritation in the trachea The incision was made along

the anterior margin of the sterno cleido mastoid muscle, and hæmorrhage arrested as the tissues were divided layer by layer, until the capsule proper of the tumor was reached Downwards the incision was carried as far as the sternum The dissection on each side of the tumor was made with great care and mainly with the points of dissecting forceps and Kocher's struma director The superior and inferior thyroid arteries were isolated and divided between two Kocher's hæmostatic forceps With great difficulty the post sternal portion was lifted from its bed, and here the minutest precautions were exercised to secure every vessel before it was divided The recurrent laryngeal nerve on the left side was exposed and drawn out of the way with blunt hooks

The tumor seemed to spring mainly from left lobe, and a part of the isthmus and entire right lobe could be left intact The tumor was separated from the isthmus by tearing, which caused considerable bleed ing, for the arrest of which a number of ligatures were required I should think at least fifty ligatures were used during the operation, which lasted nearly two hours The wound was frequently irrigated with a 1–1,000 solution of corrosive sublimate A drain was introduced into the most dependent angle of the wound, and the balance of the wound was sutured A large dressing of dry sublimated gauze and cotton was applied

The second operation of this kind was made on a man 40 years of age who had had a goitre as long as he could remember Although of considerable size, it gave rise to no serious trouble until quite recently Lately it has been growing quite rapidly, and at present he suffers from great dyspnœa after the slightest exertion The patient is very anæmic The tumor is quite firm and its lower margin can be felt The operation was the same as in the foregoing case, and that on account of firm adhesions to adjacent parts anteriorly the dissection in this locality was attended by great difficulty, as it was not easy to decide between tumor tissue and adherent parts Near the base, where no such adhesions existed, the separation proceeded rapidly and without any accidents The thyroid arteries were larger than the radial vessels I noticed that wherever it was possible the hæmostatic forceps were always applied across the vessels, which not only afforded better security in controlling the hæmorrhage, but also facilitated the application of the ligatures In both cases the trachea was found considerably compressed and flattened, but no trouble appeared from this source, and the relief afforded by the operation was prompt and lasting in each instance Both specimens on examination proved to be adenomata with cystic degeneration Both patients were reported as doing well a week later

The first day I was in Zurich I was present at a very interesting autopsy made by Professor Klebs upon one of Kronlein's patients A few days before a woman 40 years of age was brought into the hospital presenting well-marked symptoms of intestinal obstruction, which had lasted for two weeks On examination no cause for the obstruction could be found The examination was not satisfactory, as the abdomen was very tympanitic Laparotomy was performed, but as nothing could be found and the small intestines were found enormously distended throughout, inguinal colotomy was performed The operation was followed by decided relief, the abdomen collapsed and a large quantity of fæces was discharged through the artificial anus, but the patient died of collapse the next day At the post mortem examination the cause of the obstruction was found 20 ctm below the artificial anus in the shape of a narrow annular carcinomatous stricture of the colon In his remarks on the case Professor Kronlein stated that he had observed four similar cases during the time he has been in Zurich It is not unusual that such a stricture gives rise to no symptoms until suddenly symptoms of complete intestinal obstruction are developed It would be well in the future, when a similar condition is suspected, to explore if need be the upper portion of rectum and lower extremity of colon as far as accessible by Simon's method, as in case the lesion is recognized and accurately located these cases are favorable for a radical operation by excision

Professor Klebs kindly showed me his laboratory and many very valuable specimens in his collection He has just completed the first volume of his great work on pathology, which is to appear in three volumes Although somewhat advanced in years, he remains at his post from morning until evening ever ready to impart information to the seekers for knowledge If the remaining volumes are to be judged by the first his work will be the most complete and perfect text book on pathology

Dr Rohrer, Privat-Docent for Otology, is an enthusiast in his specialty He works daily from one to two hours with Prof Klebs and has prepared one of the finest collections of the comparative anatomy on the ear in the world He is also pursuing bacteriological studies with special reference to diseases of the ear I spent a profitable afternoon in his private clinic and was astonished with what care and patience he examines his patients Supplied with all modern instruments for investigation he is enabled in all cases to locate the pathological conditions with precision and on the basis of a correct diagnosis in obscure cases, he is prepared to adopt a rational and often successful course of treatment in cases heretofore considered incurable He is one of the most active and influential members of the International Congress of Otology, and if he continues in the future as he has done in the past will soon stand at the head of his specialty

DOMESTIC CORRESPONDENCE

TRANSFUSION OF BLOOD

Dear Sir —In THE JOURNAL of April 9, you published a letter from me criticising an article by Prof Hunter, of Edinburgh, on the subject of transfusion In that letter I insisted that Prof Hunter's conclusions were formulated on theories which were in dis-

pute and inconclusive, and that the published results of this operation showed it to be of permanent benefit, when successfully performed

In THE JOURNAL of July 9 and 16 is published a lecture by Prof H von Ziemssen, on "Subcutaneous Blood Injections," which fully sustains my position Prof Ziemssen says "I am convinced that in these cases (pernicious anæmia) the hæmoglobin is not merely temporarily improved, but a cure may be obtained, possibly by the action of the blood in a way unknown to us" In his opinion the therapeutic value of blood is so great as to more than counterbalance the depressing effects of chloroform narcosis, the massage, which is so severe that the administration of chloroform is rendered necessary, the pain attending the introduction of the canula from twelve to fifteen times "through a raised fold of the skin deep into the subcutaneous cellular tissue," the stretching and tearing of the tissue under the powerful massage (see THE JOURNAL, July 9, p 37), the chilling effects of the use of an ice bladder "renewed as long as the pain continues" (from two to six days), and in addition to all this, the "ecchymoses which frequently, but not always, result from the injections"

Nor is the blood, the value of which more than counterbalances all this, of unimpaired value and vitality? It has been exposed to the air, whipped, subjected to a powerful massage, and so changed that it does not take its place among the blood corpuscles of the patient, but only serves to increase the hæmoglobin We need no tables to show this Let any one interested in the subject beat some freshly drawn blood as violently as it must be treated in the defibrinization and massage to which it is subjected in the process of subcutaneous injection, and he will find, if he place it under the microscope, that the corpuscles are either partially or wholly destroyed Now, if blood be so valuable after having been deprived of its fibrin and of the blood plaques (or elementary corpuscles) exposed to the air, chemically changed (for Blundell proved, by his experiments, that blood changes chemically when out of living tissue longer than three seconds), how much more valuable would be a transfusion, in which the blood, unimpaired and unchanged—just as good as new—should be transferred to the patient's veins with no greater pain than is caused by once opening the smallest and most readily accessible vein in the venous system? This, too, without any disturbance to the heart, for the experiments of Worm-Muller have shown that where the blood is unmixed with air, if the transfusion be slow, the heart rapidly accommodates itself to wide changes in the blood pressure "without any pathological phenomena" (Ziemssen's Cyclopædia, article "Transfusion") Roussel ("Transfusion") records fifty four direct transfusions, in not one of which was there any heart disturbance

In my own experiments in the presence of Professors Vaughan and Langley, of the University of Michigan, I transfused 17 ozs of blood *rapidly* from the vein of a strong, healthy sheep into the vein of a small, weak one (which was just recovering from the effects of a broken leg) As soon as the operation was completed the animal was released, and was one of the *fleetest runners* I ever saw (Professor L attempted to catch him, without success)

But it is the almost universally received opinion that direct transfusion cannot be safely performed Immermann (Ziemssen's Cyclopædia, Transfusion) says "No instrument has yet been devised with which the operation can be safely performed" Dr T Gaillard Thomas, of New York, has said "Transfusion is an operation the theoretical importance of which all will admit, but practically it amounts to very little indeed, mainly on account of its difficulties and dangers, nearly all of which arise from the tendency of the blood to coagulate" (*Medical Record*, 1878) In another communication I propose to discuss the proposition suggested by these quotations

That blood introduced into the circulation by artificial means has a wonderful effect on both the living and the dead, is proved already beyond question Its effect upon the living is shown by the reported cases of transfusion, particularly by Roussel Its effect upon the dead was shown by the experiments of Brown Séquard "Brown-Sequard has discovered that all the nerves and contractile tissues in the brain and spinal cord, the motor and sensitive nerves and muscles of animals or organic life, the iris, the skin, etc , may, after having lost their vital powers, and their life, recover these properties again and, in some respects, be again resuscitated when blood, containing a great amount of oxygen, is injected into the arteries of all those parts Still more, he has found that when cadaveric rigidity exists in the limbs of man or animals, oxygenated blood has the power of restoring local life in those parts These experiments were made on many animals and on the arms of two decapitated men, thirteen and fourteen hours after death The more blood corpuscles and oxygen the blood injected contains, the greater the power of regeneration In one case, Brown-Séquard maintained local life in a limb for forty-one hours after it was separated from the body" (American Encyclopædia, p 735)

Now, I do not claim, from the above quotation, that transfusion can raise the dead Indeed, it is a serious question whether it can raise the living, and the results of my investigations lead me to claim far less for the operation than have some medical authorities

The question which I next propose to consider is, Can the operation be safely and easily performed?

COLD ABSCESS AND ERYSIPELAS

Dear Sir —About May 1 I was called to see Mr F , aged 78, feeble and quite fleshy, who had a large abscess over the right scapula It was opened and a large quantity of pus evacuated The skin over it was of a dark purple color, and sloughing seemed imminent, but evacuation and drainage caused it to heal without refilling Prompt recovery took place

His wife nursed him and dressed the abscess, a 10 per cent solution of carbolic acid being used A week after the abscess was opened Mrs F was taken

with facial erysipelas of a severe type, which ran a course of about 14 days Towards the last the disease attacked the right leg just above the ankle, an abscess formed and pus was evacuated, and recovery followed

The origin of the cold abscess of Mr F could not be ascertained, there was no history except of a slowly formed swelling, but the wife's erysipelas could be seemingly traced to infection from the abscess while nursing her husband A microscopic examination of the pus from the two abscesses would have been interesting It seems that septic infection is the only way to account for Mrs F 's erysipelas A D BUNBY, M D

St Ansgar, Iowa, July 15, 1887

NEW INSTRUMENTS.

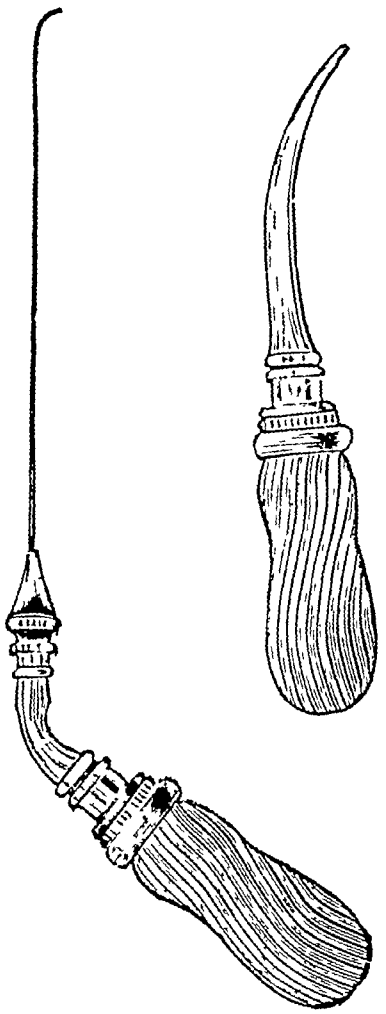
MODIFICATION OF DUNN'S DENTAL SYRINGE

Read before the Chicago Society of Ophthalmology and Otology, February 8, 1887,

BY J ELLIOTT COLBURN, M D,

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN THE CHICAGO POLI CLINIC ASSISTANT SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY, ETC

I wish to call your attention to a modification of Dr Dunn's Dental Syringe, which renders it of practical value in the treatment of lachrymal disease It is made with the curve of the Bowman probe, olive-pointed, and conical in shape The instrument can be used with or without the slitting of the canaliculus It can be more delicately manipulated than the piston syringe, and has the merit of being always ready for use In chronic catarrh of the sac, it is eminently convenient, as it enables the operator to use strong astringent solutions without danger of regurgitation into the conjunctival sac In cases of stenosis of the nasal duct it is useful as it can be entered the same as a probe and the operator can force remedies into the nose without wounding the tissues At my suggestion Haussman, McComb & Dunn, of Chicago, have added a convenient tip for medicating the middle ear, being a slight modification of Anel's syringe Altogether it makes the most convenient form of lachrymal and middle ear syringe it is light, strong and durable, capable of great force and delicate manipulation



MISCELLANEOUS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM AUGUST 20 1887, TO AUGUST 26, 1887

Lieut Col Joseph C Baily, Asst Medical Purveyor, granted leave of absence for one month Par 10, S O 191, A G O, August 18, 1887

Major W S Tremaine, Surgeon, found incapacitated for active service by an Army Retiring Board, and extension of leave of absence on account of sickness still further extended until further orders Par 9, S O 192, A G O, August 19, 1887

Major John H Bartholf, Surgeon, leave of absence extended one month Par 7, S O 196, A G O, August 24, 1887

Capt Julius H Patzki, Asst Surgeon, granted leave of absence for one month Par 15, S O 196, A G O, August 23, 1887

Capt Washington Matthews, Asst Surgeon, ordered to proceed to Phoenix, Ariz Ter, on public business, and on completion thereof, to return to his proper station Par 21, S O 195, A G O, August 23, 1887

Capt Blair D Taylor, Asst Surgeon, granted leave of absence for twenty days, to take effect on or about August 31, 1887 Par 7, S O 193, A G O, August 20, 1887

First Lieut E L Swift, Asst Surgeon, ordered to report in person to Commanding General Div Pacific, for duty with troops at Round Valley Indian Reservation Par 20, S O 195, A G O, August 23, 1887

Capt Henry Johnson, Medical Storekeeper, ordered, in addition to his present duties, to take charge of the office and perform the duties of acting Asst Medical Purveyor in New York City during the temporary absence on leave of Lieut Col Jos C Baily, Asst Medical Purveyor Par 11, S O 191, A G O, August 18, 1887

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEKS ENDING AUGUST 27, 1887

Surgeon P H Bailhache, granted leave of absence for thirty days August 26, 1887

P A Surgeon H R Carter, granted leave of absence for twenty seven days August 25, 1887

P A Surgeon H W Yemans, resignation accepted, to take effect September 30, 1887, and leave of absence extended to that date August 24, 1887

Seaton Norman, granted leave of absence for six days, on account of sickness August 27, 1887

Vol IX CHICAGO, SEPTEMBER 10, 1887 No 11

NINTH INTERNATIONAL MEDICAL CONGRESS.

INAUGURAL ADDRESS

Delivered Monday, September 5, 1887, in Albaugh's Opera House, Washington, D C,

BY NATHAN SMITH DAVIS, M D, L L D,

PRESIDENT OF THE CONGRESS

GENTLEMEN —It is my sad duty first to remind you that *death* has removed from among us *one* to whom, more than to any other, we are indebted for the privilege of having the Ninth International Medical Congress in America *One* whose urbanity, erudition, valuable contributions to medical literature and eminence as a teacher, caused him, not only to be universally regarded the most influential leader in all the preparatory work, but also *the one* unanimously designated to preside over your deliberations on this occasion

That *one* was the late Professor Austin Flint, of New York, who was taken suddenly from his earthly labors early in 1886, before the work of preparation for this Congress had been half completed The true nobility of his private and professional character, his eminent ability as a teacher, and above all the number and value of his contributions to the literature and art of medicine, had caused him to be known and esteemed by the profession in all countries And as you all remember, while the shock of his death was fresh upon us, our loss seemed well nigh irreparable, but though he has taken his departure ripe in years and full of honors, yet the influence of his excellent example and his contributions to medical science remain, and will continue to exert their beneficent influence through all the generations to come

With a full consciousness of my own deficiencies and still with a heart overflowing with gratitude, I thank you for the honor you have bestowed in selecting me to preside over the deliberations of this great and learned assembly It is an honor that I appreciate as second to no other of a temporal nature because it has been bestowed, neither by conquest nor hereditary influence, nor yet by partisan strife, but by the free expression of your own choice

Addressing myself now more directly to those here assembled, who have left homes and loved ones in other lands and encountered the fatigue and danger of travelling by sea and by land, in the name of the Medical Profession of this country I welcome you, not only to this beautiful city and the hospitality of its citizens as has been so admirably done already by the honorable representative of the Government, who has just taken his seat, but I cordially welcome you to the open arms and warm hearts of the medical men of this *whole country*, in whose name you were invited here three years since, and whose representatives are now here, side by side with you, gathered from the East, the West, the North, the South, as well as from the rugged mountains and fertile vallevs of the Centre, to make good the promise implied by that invitation

If they do not cause you to feel at home and happy, not only in the social circles and halls devoted to the advancement of science, literature and art in this city of our Nation's pride, but wherever you may choose to roam, from the rocky coast of New England on the Atlantic to the Golden Gate of the Pacific, it will be from no want of earnest disposition to do so

And now, I not only thus welcome you from other lands, but I take great pleasure in greeting you one and all as leading representatives of a profession whose paramount object is the lessening of human suffering, by preventing, alleviating, or curing diseases wherever found, and in whatever class or grade of the human family Nay, more, with profound reverence I greet you as a noble brotherhood, who in the practical pursuit of that one grand object, recognize no distinction of country, race or creed, but bind up the wounds and assuage the pains of the rich and poor, ruler and ruled, Christian and pagan, friend and foe alike

Not that every medical man does not love and defend his own country and fireside with as fervid a patriotism as the members of any other class of men But as disease and pain are limited to no class or country, so is the application of his beneficent art limited only by the number of those suffering within his reach

With a common object so beneficent in its nature, and opportunities for its practical pursuit so universal, it is but natural that you should be found searching for the most effectual means for the accomplishment of the one object of lessening human suffering, in every field of nature and in every department of human knowledge

The living human body—the chief object of your solicitude, not only combines in itself the greatest

number of elementary substances and the most numerous organs and varied functions, so attuned to harmonious action as to illustrate the operation of every law of physics, every known force in nature, and every step in the development of living matter from the simple aggregation of protoplasm constituting the germinal cell to the full-grown man, but it is placed in appreciable and important relations with the material objects and immaterial forces existing in the world in which he lives

Hence a complete study of the living man, in health and disease, involves a thorough study, not only of his structure and functions but more or less of every element and force entering into the earth, the air and the water with which he stands in constant relation

The Medical Science of to day, therefore, embraces not only a knowledge of the living man, but also of such facts, principles, and materials gathered from every other department of human knowledge as may increase your resources for preventing or alleviating his suffering and of prolonging his life

The time has been, when medical studies embraced little else than the fanciful theories and arbitrary dogmas of a few leading minds, each of which became for the time the founder of a sect or so-called school of medicine, with his disciples more or less numerous But with the development of general and analytical chemistry, of the several departments of Natural Science, of a more practical knowledge of physics, and the adoption of inductive processes of reasoning, the age of theoretical dogmas and of medical sects blindly following some more plausible leader passed away leaving but an *infinitesimal* shadow yet visible on the medical horizon

So true is this, that in casting our mental vision, to-day, over the broad domain of medicine we see its votaries engaged, some searching for new facts and new materials, some studying new applications and better uses of facts and materials already known, some of them are in the dead house with scalpel and microscope, not only studying the position and relations of every part from the obvious bones and muscles to the smallest leucocyte, in health, but also every deviation caused by morbid action or disease Some are searching the fields, the forests, the earth and the air, both for more knowledge concerning the causes of disease and for additional remedial agents, some are in laboratories with crucible, test glass and microscope analyzing every morbid product and every remedial agent, separating the active principles from the crude materials and demonstrating their action on living animals, while far the greater number are at the bed-side of the sick and wounded applying the knowledge gained by all other workers to the relief of human suffering A more active, earnest, ceaseless and beneficent field of labor, is not open to your vision in any other direction or occupied by any other profession or class of men And thus has the Science of Medicine become a vast aggregation of observed facts, many of them so related to each other as to permit practical deductions of permanent value, while many others remain isolated through incompleteness of investigations, and therefore liable to prompt, hasty or even erroneous conclusions

Indeed the most defective and embarrassing feature in the Science and Art of Medicine, at this time, is the rapid accumulation of facts furnished by the vast number of individual workers, each pushing investigations in some special direction without concert with his fellows, and without any adequate conception of the coincident lines of observation necessary to enable him to see the true bearing of the facts he evolves Hence he is constantly mistaking mere coincidences for the relation of cause and effect, and the pages of our medical literature are being filled with hastily formed conclusions and rules of practice from inadequate data

This results in part, at least, from the extent and variety of the fields of inquiry and the complexity of the problems presented for solution For nowhere else within the realms of human thought, does the mind encounter problems requiring for their correct solution the consideration of a greater number of data, than in the study of etiology and pathology To determine the appreciable conditions of the earth, air and water of any country before, during, and after, the invasion of an epidemic disease long enough to include several consecutive visits of the same, is not possible for a single individual, nor for any number of observers acting separately or without concert

Yet just this complete knowledge is necessary to enable us to separate the conditions that are merely coincident or accidental from those that are such constant accompaniments of the disease as to prove a necessary relation between them And it is only by such persistent, coincident systematic observations of many individuals, each having a definite part, and the results carefully compared analytically and synthetically at proper intervals, that the real conditions and laws controlling the prevalence and severity of epidemics and endemics can be clearly demonstrated It is not enough to discover the primary infection, or the *contagium vivum*, whether it be the bacillus of cholera, yellow fever, or tuberculosis, for abundant experience has shown that not one of these will extend its ravages in any community or country unless it finds there is a soil or pabulum congenial for its support and propagation

It is on the development and diffusion of knowledge concerning the local conditions necessary for receiving and propagating the specific infections of disease that nearly all the important sanitary measures of modern times have been based And it is on a further development of knowledge in the same direction, gained by more systematic, continuous and coincident investigation, that we shall most successfully protect our race from the pestilences that have hitherto "walked in darkness and wasted at noonday"

It was the extensive and ever extending field of medical science, the complexity of the problems pressing for solution, and still more the individual responsibility of applying the resources at command to the direct treatment of disease, that early disposed medical men to seek each other's counsel, to form groups or clubs for comparison of views and mutual improvement The manifest advantages of these

soon prompted more extended social gatherings, until at the present time a large proportion of the more active members of the profession in every civilized country are participating in municipal, district, National and International medical organizations

The aggregate benefit derived from all this active intercourse is beyond easy expression in words In the more frequent and familiar comparison of cases and views on all professional subjects in the local societies, closer habits of observation and a wider range of thought are induced while narrow prejudices and bigotry give place to generous rivalry and personal friendships In the larger gatherings, the formal preparation of papers and reports on a great variety of subjects impels their authors to a wider range of study and greater mental discipline, while the collision with other minds in discussion brings all aspects of the subject to view, enlarging the scope of mental vision, starting new trains of thought, and begetting a broader and stronger mental grasp with purer and nobler aims in life

I think I am justified in saying that no other one influence operative in human society during the present century has done as much to develop and diffuse medical knowledge, to stimulate its practical and successful application, both in sanitary measures for preventing disease and in the direct alleviation of suffering at the bedside, and in unifying and ennobling the profession itself, as has been accomplished by the aggregate medical society organizations of the world Yet their capacity for conferring other and perhaps still greater benefits, under proper management, will have become manifest in the near future And that I may accomplish the chief object of this address, I must ask your indulgence while I indicate some of the more important additional benefits in advancing medical science and saving human life through the instrumentality of our medical society organizations, and the methods by which they may be accomplished

Every experienced and intelligent practitioner of the healing art is familiar with the fact that all acute general diseases are influenced in their prevalence and severity by seasons of the year, topographical and other conditions of the earth, meteorological conditions of the atmosphere, and the social condition and habits of the people themselves The most familiar endemics vary annually in the same localities, while the great epidemics that have for ages broken over the comparatively limited boundaries of their habitats only at intervals of years, and extended their ravages from country to country and receded again to the source from which they apparently originated, differ widely in the different periods of their prevalence But in studying the essential causes of any one of these general diseases and the laws and conditions under which such causes operate, he soon finds certain factors, essential for the solution of his problems, wanting

For instance, if he wishes to identify the date of the first attack of epidemic cholera in a given locality, and the character of bowel affections immediately preceding, the ordinary statistics of mortality will give him only the date of death, which may have been from one to seven days later, or it may have been preceded by one or more cases that recovered If he is anxious to determine the reason why the disease, on entering one community, develops with such rapidity that in a few days its victims are found in every grade of the population and in almost every street, while in another it develops slowly, adhering persistently to particular classes or localities, he may find in the ordinary meteorological records the thermometric, barometric and hygrometric conditions of the atmosphere, with the direction and the velocity of the winds, but he finds nothing regarding those important though variable elements known as ozone and hydrogen peroxide, active oxidizers, or those nitrogenous products called free and albuminoid ammonia Neither do the sanitary records give the desired information concerning the composition and impregnations of the soil, or of the organic and inorganic emanations that may arise therefrom

An adequate knowledge of these absent factors relating to the condition of the earth, air and water over districts large enough to embrace localities subject to invasions of the epidemics and others known to be exempt, through a sufficient length of time to cover several periods of prevalence and periods of absence alike, is essential for enabling us to comprehend the causes that make one district amenable to the prevalence of a disease and another not, as well as the marked differences in the severity and mode of progress of the same disease at different periods in the same localities and same classes of the people The same additional knowledge would also furnish the basis for further sanitary measures of the greatest practical value

And yet it must be obvious that the cooperation of numbers of medical men directly engaged in the field of general practice, with others possessed of more practical facilities for chemical and microscopical research, is necessary for successfully prosecuting such coincident and continuous investigations as would be likely to secure the desired results Only well trained general practitioners in every locality chosen for observation could observe and record the date of the initial symptoms of acute general diseases coming under their notice, and at stated intervals collate and report them to a central committee The daily observations concerning the presence and relative proportion of active oxidizers and of nitrogenous organic elements in the atmosphere and the water, would require the selection of one or two experts in chemical and microscopical research for each locality, all making their observations coincidently in time and by uniform methods

There are included in the organized medical associations of each country the men and materials necessary for prosecuting every well defined line of inquiry, and these associations, by their stated meetings and their facilities for inter communication and concert of action, present the entire machinery needed and are only waiting for well planned and systematic use

The tendency to make the permanent medical organizations available for prosecuting work in the directions I have indicated has already been manifested to a limited extent, as may be seen in the for-

mation of the Collective Investigation Committee of the British Medical Association and of the International Collective Investigation Committee, organized during the sitting of the Eighth International Congress at Copenhagen

An earlier movement more fully of the character I have been endeavoring to explain was made by the American Medical Association in 1875[1] when a standing committee was appointed to establish in a sufficient number of localities regular coincident daily observations and records concerning all appreciable meteorological conditions including organic and inorganic elements found in the atmosphere, and the date of beginning of acute general diseases, and report the results at each annual meeting of the Association

The Committee made reports embodying facts of interest and permanent value in 1877[2], in 1879[3], in 1881[4], in 1882[5], and in 1883[6] The latter report contains among other items a complete tabulated statement of the free and albuminoid ammonia in the atmosphere for every day in the year ending Aug 31, 1883, as determined for the committee by Prof J H Long in connection with the laboratory of the Chicago Medical College The Committee is still prosecuting its work with material in hand for a still more important report at an early day The greatest difficulty encountered has been to enlist a sufficient number of active practitioners in each locality who faithfully record the desired clinical facts and report the results to the Committee But this and all other obstacles can be overcome by persevering and well-directed work

I trust no apology is needed for having embraced this occasion to attract your attention to the very important question how to make all our Medical Associations more useful in promoting the science of medicine by more complete methods of investigation, especially in directions where the coincident action of several persons in different places, is essential for success

I fully appreciate the great benefit resulting from the simple mingling of large numbers of medical men in social contact where each is made to hear constantly, whether on the street, in the hotel, or the assembly room, new suggestions, new modes of expression and to observe the physical and mental effects of the various habits and customs of the different peoples, until each one leaves the general gathering with largely increased mental activity and resources as was so happily expressed by Sir James Paget in his address to the Congress of 1881 in London And I appreciate in a still higher degree the benefits derived from the preparation and reading of papers by individuals and the discussion of important questions in all our assemblies

But for reasons I have already briefly stated, I hope to see added in every permanent general medical society, two standing committees, one, to whom should be referred for critical examination every communication claiming to embody a new discovery in either the Science or Art of Medicine, and the other should be charged with the work of devising such lines of investigation for developing additional knowledge as require the cooperation of different individuals, and perhaps societies, and of superintending their efficient execution until crowned with success

If ten or twenty per cent of the money paid for initiation and membership dues by the members of each society were appropriated and judiciously expended in the prosecution of such systematic and continuous investigations from year to year, it would accomplish more in advancing medical science directly, and indirectly in benefitting the human race, than ten times that amount would accomplish if expended in any other direction

For it must be remembered that when money is expended for material objects, even for food, clothing or medicine, such materials feed, clothe or relieve but one set of needy individuals and are themselves consumed, but the expenditure of money and time in such a way as to develop a new fact capable of practical application either in preventing, alleviating or curing disease, that *fact* does not like the food or medicine perish with the using, but it becomes literally imperishable Neither are its benefits limited to one set of individuals, but it is transmitted with the speed of the lightning over the land and under the sea to every civilized people, and whatever benefits it is capable of conferring are as capable of being applied to a million as to one, and of being repeated with increasing efficiency from generation to generation

It has been tersely and correctly stated that associated action constitutes the characteristic and predominating power of the age in which we live

It is by associated action that education in its broadest sense, religion, and civilization have been more rapidly diffused among the masses of mankind during the present century, than during any other period of the world's history

It is by the association of capital, wielded by the associated intellects of the nineteenth century, that highways of commerce have been opened over the valleys, through the mountains, across the deserts, and on the oceans, over some of which the material productions of the nations are borne by the resistless power of steam, and along others the products of mental action are moved with the speed of electric currents, until both time and space are so far nullified that the most distant Nations have become neighbors, and the inhabitants hold daily converse with each other from opposite sides of the globe

Indeed, it is only by means of such of these highways as have been constructed within the memory of him who addresses you, that you have been gathered in this hall from the four quarters of the earth, and through which an account of your doings may be daily transmitted to your most distant homes

I congratulate you on the fact that the profession you represent has taken the lead of all other professions or classes of men, in rendering available these

grand material achievements of the age, for cultivating fraternal relations, developing and interchanging knowledge, and planning concerted action for rendering human life everywhere healthier, happier, and of longer duration

This is the ninth grand International Congress in regular series within little more than two decades, and let us hope that all its work will not only be done in harmony and good order, but with such results as will add much to the aggregate of human happiness through all the coming generations

Without tresspassing further on your patience, I must ask your forbearance with my own imperfect qualifications, and your generous assistance in the discharge of the responsible duties you have devolved upon me

ORIGINAL ARTICLES.

THE SPECIFIC GRAVITY OF THE URINE, AND ITS RELATIONS TO STRUCTURAL DISEASES OF THE KIDNEYS

Read before the Chicago Medical Society, September 5, 1887

BY CHARLES W PURDY, M D,

HONORARY FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS AND SURGEONS KINGSTON

The physical characters of the urine have received the most careful consideration by physicians, even in the remotest periods of medical antiquity They did not escape the keen observation of the great founder of the Coic school, for indeed Hippocrates taught his followers to carefully observe the amount, the color and the clearness of the urine, and the differences in the appearance of the urinary sediment as indications of disease of the urinary organs We are informed that " he even endeavored to demonstrate the influences of various foods and drinks on the constitution of the urine " Whatever may be said of the conclusions drawn from these observations—and considering the dawning faintness of scientific light in that remote period, surely but little of accuracy could be expected—yet the correctness of the observations themselves by the great father of medicine have scarcely since been questioned, indeed many of them have been handed down to us as indisputable and axiomatic truths

To Avicenna, the Arabian, belongs the credit, early in the eleventh century, of first having directed attention to the influence exerted by external circumstances over the physical characters of the urine

Bellini, of Florence in the latter part of the seventeenth century showed by evaporation and subsequent dilution of the urine that the variations in color were due to alterations in the proportions of its contained water and solids It was about this time that the light of chemistry began to illuminate this heretofore darkened field of research, and then began for the first that true and scientific progress which has resulted in our present greatly perfected knowledge of the physiology, chemistry and microscopy of the urine

It is however, greatly to be feared that with our greater knowledge of the chemistry and microscopy of the urine, we are coming more and more to rely upon these too exclusively and thus very often to lose sight of the valuable suggestions afforded by a study of the physical characters of the urine

The object of this paper is to point out the relative value of the knowledge available from observation of the physical characters of the urine in the diagnosis and treatment of diseased conditions of the kidneys, as compared with the chemistry and microscopy of the urine, and I shall for the most part limit what I have to say upon this subject to the consideration of the specific gravity of the urine

The mere presence of albumin in the urine I believe has been vastly overestimated in value as a symptom of renal disease Indeed it only assumes its true importance when taken into consideration with other conditions quite as valuable in significance —if not more so—such as the presence of casts in the urine or the specific gravity of the latter I believe indeed that few people pass through life without at some time, for a longer or shorter period becoming the subjects of albuminuria and yet the proportion who ultimately become the subjects of organic disease of the kidneys is extremely small On the other hand as I have previously shown[1] by statistics of 259 cases of chronic Bright's disease—all of them hospital cases in which the diagnosis was verified at the autopsy—that albumin was present in the urine of 68 of the cases only, leaving 191 cases—about 74 per cent —in which albumin was absent As a positive or negative symptom, therefore, albuminuria is of value only when taken into consideration with other symptoms, and perhaps none of these are more important than the specific gravity of the urine I have no hesitation in stating my belief that the specific gravity of the urine, if carefully and intelligently observed, will afford quite as valuable diagnostic evidence of the presence of renal disease as will albuminuria, while in a prognostic point of view it will in *all cases* prove by far the more trustworthy

Before it is possible to thoroughly comprehend the relations which exist between the specific gravity of the urine and diseased conditions of the kidneys, it shall first be necessary to become familiar with the normal standard of specific gravity of the urine, as well as the variations to which it is subject when the kidneys are free from disease In discussing these points I shall make use of two terms, viz , *the apparent specific gravity of the urine*, and *the real specific gravity of the urine* By the term " apparent specific gravity of the urine" I shall in all cases mean the specific gravity of the urine as it is when passed, without reference to the daily quantity of urine excreted By the term " real specific gravity of the urine" I shall always mean the specific gravity of the whole 24 hours' product, corrected relatively upon the basis of 50 ounces

We shall see that there are numerous conditions and influences compatible with perfect health which vastly change the apparent specific gravity of the

[1] Pre Albuminuric Stage of Bright's Disease Chicago Med Jour and Examiner May 1885

urine and therefore in order to avoid being mislead by such influences we must take the relative specific gravity compared with the normal volume of the 24 hours product, for such alone can give us information of a trustworthy character Moreover, the specific gravity of the urine must always be taken from a part of the *whole 24 hours' product* in order to furnish information of any definite value, because the urine is subject to almost hourly variations in quantity and in specific gravity, and it is only at the end of 24 hours that the cycle of changes becomes completed, and then we may get the sum or product of the whole Furthermore, if we desire to obtain very accurate results, these observations must be extended over weeks

Assuming the condition to be that of adult health the average individual should excrete 50 ounces of urine of specific gravity at 1020 If the specific gravity varies materially from this standard, it will be found to be due to one or more of the following conditions The quantity of urine may be considerably increased or decreased from various causes, and this causes a variation in the apparent, though not in the real specific gravity of the urine The quantity of the urine may become increased from augmented blood presence, as from the use of large quantities of aqueous drinks, the moderate use of alcoholic drinks, which abstract the water from the tissues and overfills the vessels, from cold which contracts the cutaneous vessels and overfills the visceral circulation, from diuretics, more especially those that act upon the heart, as digitalis The quantity of urine may become decreased in health from habitual use of small quantities of fluids, when the skin and lungs are over active as in hot weather, and from diminished general or local blood-pressure The changes in the specific gravity of the urine due to alterations in the quantity are of an inverse degree to the increase or decrease in the volume of urine secreted The change in the specific gravity of the urine, then, is merely the result of the alteration in the proportions of the solid and aqueous elements of the urine, and therefore it is apparent and not real, as gauged by the normal product of 50 ounces

If we take 10 ounces of urine of a normal specific gravity (1020) and evaporate it down to 5 ounces it will then be found that the specific gravity will be doubled (1040) If now 5 ounces of distilled water be added the normal specific gravity, 1020, will be restored Again, if 10 ounces of distilled water be added to the 10 ounces of urine, the specific gravity of which is 1020, the 20 ounces product will give a specific gravity of 1010 Thus we may go on diluting or concentrating at will, and the specific gravity will constantly maintain an exact inverse ratio to the aqueous increase or decrease The solids of the urine are unchanged, as may be proved by entire evaporation of the aqueous urine, the solid residue being subsequently dissolved in the original volume of water lost by evaporation will give the original specific gravity, 1020

Now precisely the same relations obtain in the secretion of urine by healthy kidneys under the varying conditions just named The quantity of solids remains practically unchanged, while the quantity of fluid (water) is subject to the variations brought about by increased or decreased blood-pressure Since these alterations in blood-pressure are usually transient, and always variable, so these variations in the specific gravity of the urine are never permanent, but oscillate above and below the normal standard In diseased conditions of the kidneys, however, the changes both in the quantity and the specific gravity of the urine are permanent, and, moreover, as a rule to which there are very few exceptions, the relations of these alterations is not inverse but direct

We have next to consider the conditions which give rise to variations of the specific gravity of the urine secreted by healthy kidneys which are not dependent upon alterations in the quantity of the urine

Food—The character and quality of food directly influences the amount of solids of the urine, and thus cause variations in the specific gravity of the latter The meals augment the solids and increase the specific gravity of the urine, and hence, *ceteris paribus*, the specific gravity of the urine is higher after food than at other times of the day The habitual overindulgence of the appetite tends to induce a permanent increase in the specific gravity of the urine Foods rich in nitrogen, such as lean meats, furnish a relatively large amount of waste which it is the function of the kidneys to eliminate, and therefore overindulgence in such foods favors a rise in the specific gravity of the urine On the other hand, spare eaters, more especially of meats, usually secrete a urine of somewhat lowered specific gravity

Exercise hastens tissue changes, and furnishes an increased amount of solid urinary excreta We may therefore expect increased specific gravity of the urine in those undergoing active muscular exercise, and the contrary during periods of muscular quietude

The specific gravity of the urine furnishes us data from which we can calculate the amount of solids discharged by the kidneys Several rules have been laid down for this (*a*) If the last two figures of the specific gravity of the urine be multiplied by 2—the coefficient of Trapp—or by 2 33, the coefficient of Haeser—the product will approximately represent the number of grains of solid urine in each 1000 c c (38 fl ℥) (*b*) A still more simple rule mentioned by Oliver[2] is to multiply the last two figures of the specific gravity by the number of ounces of urine, and the product will approximately represent in grains the solid urine discharged in 24 hours

The amount of solids excreted by the kidneys furnishes us with a true gauge of the functional capacity or adequacy of the kidneys, which in health varies but slightly from the normal standard, save under the conditions already considered In disease of the kidneys, however, we have a most marked variation in the solid urine, and consequently in the specific gravity of the latter

This brings us to the consideration of the more practical part of our subject, viz, the influence of diseased conditions of the kidneys on the specific gravity of the urine For general guidance I would lay down the following general rules

[2] Bedside Urine Testing, 3d edition London

1 That all structural diseases of the kidneys cause a decrease in the quantity of solids excreted with the urine

2 That if measured by the normal quantity of the urine (50 ounces) the specific gravity of the urine is decreased by all structural diseases of the kidneys

3 That the decrease, both of the solids and specific gravity of the urine, bears a direct relationship to the extent of each and every lesion of the kidneys

Bearing in mind the foregoing rules we shall be able to comprehend now the value of the information devisable from the specific gravity of the urine It often gives us more trustworthy information than does the presence, or the quantity, of albumin in the urine as to the existence or otherwise of a given renal lesion, and always so of its extent, its weekly progress, its probable chronicity, or otherwise, and finally its progress towards death or recovery

The relations between the specific gravity of the urine and each of the more common organic diseases of the kidneys will now be briefly considered individually

Acute Diffused Nephritis in all its forms—scarlatinal, puerperal, toxic, including exanthemic, metastic, as that arising from cold applied to the skin, burns, and extensive cutaneous lesions, all these are accompanied by the excretion of urine much reduced in solids The apparent specific gravity in these cases is high, because the reduction in the fluid urine is much greater than in the solids The apparent specific gravity of the urine in these cases may reach as high as 1035 to 1040 The average daily quantity of the urine in acute stages of diffuse nephritis is 300 to 400 c c Now, if we take a sample of urine in a case of acute diffuse nephritis reaching the highest specific gravity, 1040, and if we restore the deficiency of the water—which we have just indicated to be on an average three-fourths—we will get a fluid of the specific gravity of 1010, which represents the highest *real* specific gravity of the urine in these cases The high specific gravity of the urine in these cases is therefore only apparently so, and is merely the result of concentration of the urine If ordinary urine of normal specific gravity be evaporated down to the same volume (three fourths), the specific gravity of the urine reduced by evaporation would be much higher than is ever observed in acute diffuse nephritis The doctrine commonly taught that the specific gravity of the urine is actually increased in these conditions is likely to mislead the student, because such a statement carries with it the presumption that the solids excreted by the kidneys are also increased, whereas, as a matter of fact, they are greatly decreased, and this decrease is one of the chief sources of danger to life from uræmia The urine then in cases of acute diffuse nephritis while apparently of higher specific gravity than normal, is yet actually, as measured by the normal volume of urine, much below the normal standard, and if the deficiency in the fluid urine be made up, the specific gravity will in every instance be found to be both apparently and actually below the normal

If improvement occur in these cases the apparent specific gravity of the urine becomes decreased, but the actual specific gravity, as gauged by the normal volume of urine, becomes increased This is due to the fact that with improvement in the renal inflammation comes an increase in the quantity of the fluid urine, which lowers the apparent specific gravity of the urine But improvement in the renal inflammation also permits an increased excretion of solids by the kidneys, and consequently a rise in the real specific gravity as measured by the normal volume of urine If improvement continue the disproportion between the apparent and real specific gravity of the urine diminishes, and when they no longer vary, but coincide, the healthy state of the kidneys is restored

If we restore the aqueous deficiency of the urine in these cases, and observe the actual specific gravity of the urine from day to day, it will furnish us with evidence of the most positive nature as to the extent and intensity of the renal inflammation, as well as of the progress of the disease towards recovery or otherwise, and surely such information is in every way worthy of the trifling pains necessary for its acquirement

Chronic Diffuse Nephritis is accompanied by a decrease in the specific gravity of the urine, and this decrease is both apparent and real The normal volume of the urine is little if any reduced, indeed, in the late stages it is considerably increased If the case be an outgrowth from acute nephritis the reduction of the specific gravity is marked from an early period, because the acute disease has left the kidneys extensively damaged, almost from the beginning Taking, for example, one such case from my notes, I find recorded in May and June, 1884, five months after the acute attack, that the specific gravity of the urine averaged 1012–1014 The case has been under my constant observation and treatment since, and during the last two months, June and July, 1887, the specific gravity of the urine has averaged 1010 It will be noted that the reduction in the specific gravity of the urine has only been two or three degrees in three years, too trifling, it may be thought by some, to afford any practical information On the contrary, it teaches me the most substantial and important information of the progress of my case It indicates to me that, by means of diet and medication, I have retarded the advance of extensively involved kidneys for three years, and moreover postponed renal contraction, as is doubly attested by the absence of cardiac changes and by the fact that the average volume of the urine remains but little if any above normal

In those cases of chronic nephritis, on the other hand, which begin insidiously and independent of acute attacks, the specific gravity of the urine at first is but little below the normal, either apparently or actually Gauged by the normal volume of urine, it is usually not lower than 1017 to 1019

If the specific gravity of the urine be noted from time to time in these cases, it will furnish pretty substantial information as to the progress and extent of the disease From month to month, or at least from year to year, if the progress of the disease continues

unchecked, the specific gravity of the urine will become more and more reduced Finally, in the last stages of the disease, from whatever cause it arises, the specific gravity of the urine becomes very much reduced Contraction of the kidney begins, and with this cardio-vascular changes usually occur and result in increasing the volume of urine above normal It is not uncommon for the specific gravity of the urine under such circumstances to range as low as 1006 to 1008 I am, indeed, led to believe that contracted kidneys resulting from chronic diffused nephritis furnish urine of considerably lower specific gravity than do the granular contracted kidneys, or the so-called kidneys of interstitial nephritis In the former case the lesions are more diffuse, and involve more of the secretory structure of the organs, while in granular contracted kidneys the changes begin in circumscribed areas of the organs, and rarely become general

Cirrhosis of the Kidneys, or primary granular atrophy, results in excretion of urine both apparently and really below normal in specific gravity The decrease is not marked at first, indeed, it is stated in some cases to be slightly above normal I believe that in such cases the patients are large meat consumers, for upon ordinary diet I have always found the urine at least from one to three or four points below normal in the early stages of the disease As is well known, this disease is very tardy in its progress under ordinary circumstances, and therefore it may be several years before the specific gravity falls very markedly In the middle stages of the disease, with commencing cardiac changes, I have observed the usual range to be 1014–1016 In the late stages of the disease the specific gravity of the urine usually descends to 1010 or thereabout, and I believe the patient rarely survives long if the specific gravity of the urine continues below that point

The lowered specific gravity of the urine in these cases is a diagnostic point of great importance, and it has more than once saved me from error in diagnosticating Indeed, while preparing this paper, a lady from the interior of the State consulted me as to the condition of her kidneys The urine was absolutely free from albumin, as proved by repeated trials with the most delicate tests No casts were found by usual methods of examination The specific gravity of the urine was constantly below normal, ranging from 1013 to 1015, and this fact more than any other made me suspicious, and more thorough investigation was determined upon A large quantity of urine was secured and charged with resorcin to prevent change, and this was set aside in a conical glass *for three days* in order to insure the settling to the bottom of any casts that might be present In the sediment from this there was no difficulty in finding hyaline and finely granular casts in every slide examined The sphygmograph showed very marked tension in the arterial system, the patient rises at night to urinate pretty regularly, and there has been a dyspepsia and diarrhœa of late which I have no doubt are mild uræmic symptoms Now, without the continued low specific gravity of the urine observed over a number of days under varying conditions, I should hesitate to pronounce the case one of renal cirrhosis, but such it undoubtedly is

It is doubly important that the specific gravity of the whole 24 hours' product of urine be taken in the disease under consideration, because it will usually be found that the specific gravity of the urine in these cases is higher during the day than at night This depends in part at least upon the fact that in most of these cases much the larger part of the urine is secreted at *night*, a circumstance I am unable to account for satisfactorily, unless it be, as the late Dr McBride, of New York, assured me from his personal observation, that the vascular tension is higher at night than in the daytime

Amyloid Degeneration of the Kidneys causes the excretion of urine both apparently and actually below normal in specific gravity As a rule the quantity of urine is somewhat increased, and in some cases it is considerably so This, however, varies in different cases, but in all, if the specific gravity be gauged by the normal quantity of urine, it will be found more or less below the normal standard

The specific gravity of the urine in amyloid disease of the kidneys furnishes very important information as to the extent and progress of the disease, and moreover, it affords valuable prognostic data Perhaps I cannot better illustrate this point than by citing two cases from my notebook The cases were very similar in all respects, save that one of them was much farther advanced than the other They each came under my observation about the same time—case 136 on April 13, 1886, and case 142 on May 7, 1886 They were each the result of syphilis Case 136 was farther advanced, and over two years before coming under my charge was treated for a greatly enlarged liver and spleen (undoubtedly amyloid) The specific gravity of the urine when he came under my observation was 1012, and the quantity of albumin in the urine was 30 per cent volumetric measure In the other case, 142, the specific gravity was 1019 The quantity of albumin in the urine was 40 per cent volumetric measure, and there was slight dropsy of the legs below the knees Now it is important to note that, if we were to be guided by the albuminuria, we should conclude that in case 142 the disease was the more extensive and serious, but the specific gravity of the urine pointed to a more recent and less extensive invasion of the kidneys in case 142 than in case 136, and so the subsequent history proved

The cases were the more similar in the facts that in each the patients could not take large doses of iodides, and they were therefore treated precisely alike, for the most part by small doses of potassium iodide combined with ammonium muriate Now while each of these cases has steadily improved, and probably will ultimately recover, case 142 has made the more rapid improvement, and is, indeed, now on the verge of recovery, while case 136 is not so far improved as to make it altogether certain of the ultimate result My last notes of case 136 show a specific gravity of urine ranging from 1014 to 1016, while the quantity of albumin ranges from 10 to 16

per cent volumetric measure My last notes of case 142, taken about the same time, show the specific gravity of the urine to range from 1019 to 1020, and a range of albumin of from 4 to 6 per cent volumetric measure It seems to me from a comparison of these two cases, that nothing could be more conclusive as to the value of the knowledge elicited by observation of the specific gravity of the urine in such cases It here corrected the false impression likely to arise from superficial examination, namely, that in case 142, with a higher grade of albuminuria, and the presence of dropsy (which was absent in 136), the case was the more serious, and it pointed out unerringly that it was the less extensive, less advanced, and more amenable to treatment

In the late stages of amyloid degeneration of the kidneys, the specific gravity of the urine ranges very low, perhaps lower than in any other renal lesion Usually it is below 1010, and I have in one case observed it as low as 1004 The quantity of urine is more or less augmented in this stage of the disease, so that the real specific gravity of the urine is somewhat higher than the apparent specific gravity

Cyanotic Induration, or venous congestion of the kidneys, causes the secretion of urine of apparent specific gravity higher than normal—1025 to 1035 The volume of urine excreted in 24 hours, however, is considerably below the normal If the specific gravity be gauged by the volume of urine secreted, the former will be found to fall slightly below normal

The anatomical changes in the kidney in this condition are never very marked—never sufficiently so to cause death—and therefore the reduction in the specific gravity of the urine is never so marked as in most other organic diseases of the kidneys

Suppuration of the kidneys, from whatever cause, tubercular, septic, or mestatic, causes the secretion of urine of low specific gravity both apparent and real For the most part this reduction is marked almost from the beginning, ranging as low as 1012 to 1010 A knowledge of this fact throws valuable diagnostic light upon the probable extension or otherwise of pyelitis Thus, in a given case of pyelitis if the specific gravity of the urine remain about normal the case is probably uncomplicated so far as the kidneys are concerned On the other hand, if the specific gravity of the urine be decidedly reduced say to 1010 it indicates that the kidneys share in the suppurative process The quantity of pus in the urine affords no trustworthy information of a diagnostic character in these cases, for it may be comparatively small in quantity when the kidney is involved, or it may be large in quantity when the suppuration is confined to the renal pelvis Moreover, with regard to renal casts, we cannot always rely on their absence as furnishing trustworthy evidence that the kidneys are uninvolved, because the urine is often alkaline in pyelitis, and casts are rarely if ever found in alkaline urine, the reasons of which I have some time since pointed out [3] It will therefore be perceived that the specific gravity of the urine renders most valuable information in these cases

It would be exceedingly interesting and profitable to pursue this subject beyond the limits prescribed by the heading of this paper, to inquire into the variations of the solid urine, and consequently of the specific gravity of the latter in the various morbid conditions of the system generally, such as anæmia cachexia, syphilis, and fevers, as well as outside local diseases, as those of the liver, stomach, lungs, and inflammations Each of these, as is well known, causes a decided variation in the solids and specific gravity of the urine, and indeed these must be taken into consideration when present if the condition of the kidneys is in question But such inquiries would lead us into that vast complex of chemico regressive changes in the system at large, including the physiology of metabolism, a subject altogether too extensive for the necessary limits of this paper, and moreover quite beyond its scope Before closing, however, it may not be improper to briefly consider the subject of so called *functional albuminuria* and its relations to the specific gravity of the urine.

If the doctrine which I have sought to elucidate in this paper be correct, namely, that only those conditions of the kidneys attended by actual anatomical change result in reducing the specific gravity of the urine, then it would naturally enough be expected that in functional albuminuria, in which the kidneys are not essentially damaged, the specific gravity of the urine should not become reduced below the normal standard So true, indeed, have I found this sequence of events in practice that I have adopted it as an axiom I have therefore come to regard the following as a safe rule for guidance, viz that if the actual specific gravity of the urine be not reduced in a given case of albuminuria, the case is one of functional albuminuria

Perhaps I can not better illustrate the strength of my confidence in the diagnostic value of this rule than by the statement that in doubtful cases, if the specific gravity of the urine remain constantly at or above normal over any extended length of time, I should not hesitate to diagnosticate the absence of renal disease, even were albumin constantly present in the urine It might indeed be true that the constant presence of albumin in the urine, betokend changes in the circulation of the kidneys which ultimately might result in permanent organic change in those organs But whether such be the true condition, or that the kidneys be already organically damaged, the mere presence of albumin in the urine would not reliably indicate It is here precisely that the value of the specific gravity of the urine as a diagnostic indication appears, for when not below the normal standard it indicates that the organs are excreting the normal amount of solids, which diseased kidneys are incapable of doing for any continuous length of time

The specific gravity of the urine then in functional albuminuria is never below the normal standard, moreover, according to my observations in many of these cases it marks considerable rise above it, reaching 1022 to 1030 This latter fact has raised

[3] Bright's Disease and Allied Affections of the Kidney pp 104 and 219

many interesting questions in my mind, which I can at present only mention, notwithstanding their probable deep importance

1 What is the interpretation of this apparent increased functional activity of the kidneys in functional albuminuria?

2 Does the cause lie in the kidney itself, or is it the expression of some change of function in a remote organ, or is it the result of changes in the normal metabolism of the blood?

3 What are the relations of this increased specific gravity of the urine to functional albuminuria?

We may perhaps assume that the cause of the increased specific gravity of the urine, and perhaps of the albuminuria itself, are external to the kidneys, since, as has been shown, disease of those organs invariably results in reducing the specific gravity of the urine May not regressive changes in the economy furnish not only an excess of solids to be eliminated by the kidneys, but also in the splitting up of organic compounds result in the formation of a proteid so altered as to permit its escape through the renal filter, while yet not sufficiently altered to change its properties of responding to our ordinary tests for albumin?

There are a number of circumstances favoring such a view Our lack of knowledge of the chemistry of proteids or albumins, together with the well-known facts that they are capable of very great changes in the line just suggested, favor this view It is well known, for instance, that when albumin has taken certain regressive steps in organic metamorphosis, it is at once eliminated by the kidneys, as is observed in peptonuria and propeptonuria Now, may not less marked changes in proteids—say an intermediate step between albumin and peptone—result in the formation of a proteid which answers to all the properties suggested? It seems to me that such is quite possible, if indeed not probable

In a very valuable article on "Functional Albuminuria and its Relation to Hæmoglobinuria" Dr Ralfe,[1] of London, has made some suggestions on the close relationship between accelerated metabolism of the blood—"increased hæmolyses"— and functional albuminuria

As is now known, the red corpuscles of the blood are broken down in the liver The hæmoglobin is converted into pigment and urea in health The albuminous element of the blood corpuscles is converted in the liver into urea ordinarily, but if the destruction be abnormally great Dr Ralfe believes that "a large portion of the albumin passes off by the kidneys" Increased hæmolysis would undoubtedly account for the rise in the specific gravity of the urine in these cases, for with increased hæmolysis we have increase of urea, and the latter constitutes about one-half of the solid urine

Now to the various laws formulated in this paper I am aware of but one exception, and that occurs in cases of chronic Bright's disease combined with diabetes mellitus The occurrence of such a combination is, I believe, much more common than is generally supposed It is true that we are accustomed to find in chronic diabetes small quantities of albumin in the urine, and this is usually attributed to the irritation in the kidneys induced by the excretion of sugar The number of cases of diabetes, however, which have come under my observation accompanied by slight albuminuria and which have subsequently proved to be conjoined with chronic Bright's disease have induced me to adopt the following rule In every case of diabetes accompanied by slight albuminuria, if the patient's age be over forty years, search carefully for evidences of contracting kidney The investigation will present points of unusual difficulty, since the increased volume of urine greatly lessens the chances of discovering renal casts—which are indeed always sparse and difficult to find in this disease The vascular tension is markedly increased in diabetics, which takes away another differential diagnostic prop in such cases, and lastly, as already indicated, the specific gravity of the urine is much above normal It will therefore be observed that the investigation must be most thorough in these cases

The normal urinary solids, as we have seen, are always reduced in chronic Bright's disease, and therefore ordinarily the specific gravity of the urine falls below normal The excretion of sugar, however, often to the extent of 25 to 40 grains in each ounce of urine in diabetics, more than counterbalances the deficiency in solids induced by interstitial nephritis, and therefore the specific gravity of the urine must necessarily rise considerable above the normal standard when the two diseases occur in conjunction It will not answer, therefore, always to attribute the slight albuminuria in diabetes to simple renal irritation, or consequences the most grave and disastrous, which might otherwise be averted, will sometimes overtake these cases

SUDDEN DEATH IN LABOR AND CHILDBED

Read before the Section on Obstetrics and Gynecology, at the Thirty eighth Annual Meeting of the American Medical Association, June, 1887

BY FAYETTE DUNLAP, M D,

OF DANVILLE, KY

On January 14, 1887, I was summoned to attend a lady, aged 24 years, in her first confinement I had been engaged some months before, and by reference to my visiting book I find that she was expected to be confined on January 27 The note summoning me stated that there had been a slight hæmorrhage from the vagina for several hours, and that a premature delivery was imminent An examination proved that labor had begun, and the os was dilated to an extent to admit the index finger There were no distinct contractions, but the os was slowly dilating, and very satisfactorily The hæmorrhage continued constantly but scantily I ordered a warm vaginal douche, left the house and returned after four hours There had been some progress made, the parts were splendidly lubricated, the pains coming on periodically and increasing in force—in a few words, the labor was progressing naturally

I retired in an adjoining room at 10 P M with instructions to be called at 2 A M At this hour my patient was sleepless, suffering acutely, and the expulsive efforts very feeble, whereupon I gave hypodermatically ⅙ gr morphia and $\frac{1}{150}$ gr atropia She slept quietly for a short time, and by 7 A M the contractions began in earnest From the beginning of labor the suffering was acute, yet the woman showed no evidence of exhaustion and was very hopeful of a satisfactory issue out of her confinement I gave 30 gr of chloral *per rectum*, as the rim of the os was very sharp and unyielding and the parts becoming dry I could not perceive that it had the least effect locally or constitutionally, and repeated the hot water douche at 11 A M

At 1 P M the delivery was completed and the woman seemingly in unusually good condition, considering the number of hours she had been the victim of acute suffering At no time was there the slightest despondency or evidence that her nervous system was influenced by it The perineum relaxed well, and there was no more than the customary amount of laceration for first labors The placenta was expelled without traction or great amount of compression, and it is absolutely certain that there was no bleeding of consequence I gave my patient my undivided attention for twenty minutes or more, and save a pulse-beat of about 100 and very great prostration there were no unfavorable symptoms She had not moved from her position and was breathing tranquilly

I was preparing to leave the room when she asked me to return, as she felt as if about to faint I instantly thrust my hand into the vagina, expecting hæmorrhage, but found the womb firmly contracted and plainly to be outlined above the pubes Dyspnœa, nausea and a turbulent tossing about in bed began The second sound of the heart was lost, and the organ in a flutter and not to be counted I grasped the shoulders and lowered the head almost to the floor, and in a few seconds consciousness returned, and with it an improved tone of the heart-beat I replaced her quietly in bed, and gave 1 ounce of brandy and had the body warmed At this juncture I despatched a messenger for a consultant, and in a few minutes Dr McMurtry arrived As the heart's action was feeble and the countenance livid, I gave every few minutes brandy hypodermatically for an hour

The tone of the heart's beat would improve and remain strong a few moments at a time, and would then gradually fade away and syncope would again follow The dyspnœa continued, the cyanosis was alarming, and the surface was shrunken and freely perspiring Precisely four hours after the first syncopic seizure the woman suddenly lifted herself in bed, uttered a faint scream and fell back dead Her mind was clear up to the moment of death

In prefacing my remarks upon this case it may be well to state that is my custom to make an analysis of the urine of my pregnant patients, usually about one month before confinement As there was considerable œdema of the ankles, I examined the urine three times microscopically and chemically She was a strong, robust, hopeful person, and had a remarkably fine family history

This sad tragedy, the first one that I had witnessed, made a deep impression upon me, and I repaired at once to all the obstetric literature at my command for some explanation of this unexpected occurrence. The very meagre amount to be found in even the most popular and practical works was a matter of surprise Leishman gives about one fourth of a page, and simply says that very rarely a patient suddenly dies in childbed from some unknown cause, such as shock, heart failure or exhaustion Playfair gives something more, Cazeaux and Ramsbotham and Parvin nothing at all It remains for Lusk, who had an experience similar to my own just prior to giving his work to the press, to give especial attention to this subject A few weeks ago I reported this case to the Medical Society of my village, and nearly every practitioner had had one or more lying in women suddenly die with the assemblage of symptoms above related A calamity of this kind, if taking place only once on an average in the professional life of every general practitioner, deserves more attention than has been given to it

This, and a like experience to be related hereafter, brought the matter prominently forward in my studies In prefacing his remarks upon the class of cases to which this history belongs Winckel says "He who has once seen a puerperal woman happy and joyous in the expectation of soon leaving her couch, then directly afterwards has found her a corpse, will be able to comprehend the truth of Hervieux's words 'In the twinkling of an eye all the calculations of prudence are set at naught, the most untiring vigilance, the best established rules of hygiene, all the varied resources and ingenious combinations of therapeutics, are shattered against an invisible rock,'" then adds with a tone of despondency "The only thing which remains for the physician after such a depressing occurrence is to seek out the cause of the sudden death"

In this search it is my purpose to pass over consideration of rupture of the uterus, apoplexy, the snapping asunder of an aneurism and post-partum hæmorrhage, and following the example of Lusk, confine myself to entrance of air into the lungs, shock, exhaustion and embolism

The surgeons have taught us that the entrance of air into the venous circulation is fraught with danger This accident is most likely to occur in opening the veins of the neck, the act of inspiration encouraging the entrance of a volume of air into the open venous mouths The sudden emptying of the womb produces a like result, and it is plainly to be understood how air can find its way into the open veins of the placental site This is particularly true in cases in which the labor has been unduly prolonged and the uterus left in a relaxed condition It has frequently happened that sudden death has occurred before delivery was accomplished, this being due to the fact that a partial separation of the placenta has left the venous sinuses standing widely open The plan of inducing premature delivery recommended by Kiwisch, then, is particularly perilous

I can recall the particular features of a case in my practice which seems to illustrate the dangers from this source I placed my patient in the Sims' position, introduced his speculum in order to remove a four months' fœtus that was firmly held by the rim of the os uteri I grasped the mass with the placental forceps and easily dislodged it After removing the secundines with the forceps I introduced the nozzle of a Davidson's syringe and forced in a stream of water to clear the womb of clots and débris generally Pure, very warm water only was used The os seemed sufficiently relaxed to allow an unobstructed return of the water thrown in While this was in progress the woman began to breathe heavily, spoke in a whisper, and became cyanotic She felt as if a heavy weight was bearing her down The effort to breathe was violent, and she breathed more rapidly than I thought it possible for an adult to do The heart was beating tumultuously, but strong enough I used brandy freely hypodermatically, and even ventured upon giving 20 drops of liq ammon in one syringeful After lying a few minutes in a relaxed and semi-unconscious state she slowly revived and made a prompt recovery Sir James Paget tells us that it is possible for a considerable amount of air to enter the circulation, and if it is properly disposed through the lungs it will be speedily absorbed and do no damage I have always believed that the sudden and firm contraction of the uterus caught above the internal os a volume of air that had been forced in by the syringe, and it found its readiest exit by way of the venous sinuses My father, who was holding the speculum, remarked that the symptoms presented an exact counterpart to those in a man dying on the operating table from the entrance of air while undergoing an operation for exsection of a portion of rib

Lusk quotes an interesting case reported by Kezmansky, of Budapest The patient was 36 years of age, and in labor for the fourth time An excessive amount of fluid was recognized The patient entered the hospital at 10 A M At 3 P M she lay upon her left side, and the bag of waters protruding from the vulva Spontaneous rupture occurred and a gallon of water escaped Five minutes later the patient suddenly threw back her head, gasped a few times for air, the face became livid, and respiration was arrested In scarcely two minutes Dr Liebman was at her side, but the pulse was extinct The forceps were applied and an asphyxiated child was delivered The heart was feebly beating, and the woman died before delivery was completed At the post-mortem examination, twenty hours after, pale reddish-brown blood, mingled with bubbles of air, was found in the uterine veins, vena cava, lungs, and especially in the pulmonary artery In the vena cava, columns of blood and air alternated Kesmansky makes the following statement in his report "The patient lay upon her left side with her knees drawn up in nearly the Sims' position, with the vulva elevated above the concavity of the abdomen As the membranes ruptured there was a sudden diminution of the intra-abdominal pressure, so that the air entered through the open vulva between the collapsed membranes and the uterus The ensuing retraction of the uterus forced the head to the os externum, and caused the placental separation The next contraction caused the uterine air to escape by the only channel that was possible, viz by the open mouths of the placental veins "

In the *St George's Hospital Reports*, vol vi, Cordment reports two cases From the position of the patients at the time of delivery it was an easy matter for air to gain admission Post-mortem examination demonstrated that the larger veins in both the abdominal and thoracic viscera had bubbles of air in them, and in the right side of the heart The brain was anæmic and contained frothy serum In addition to these symptoms was the extreme pallor of the surface, feeble pulse, jerky and rapid respiration and speedy collapse

It is thus demonstrated that Kiwisch's plan of inducing premature labor by the forced stream of water, that to admit a sudden volume of air into the womb while the sinuses are open, to allow the woman to be delivered in the standing position, to deliver her in the knee-chest position, as suggested by Ludwig under certain contingencies, are dangerous in the extreme In my case I can never be certain that air in the veins was the cause of the alarming condition, but I shall always believe so The sudden onset of the symptoms, their sudden disappearance and the favorable position of the patient, are the only evidences I have to offer to sustain my belief

I now turn to a consideration of shock or exhaustion as a cause of sudden death in childbed The phenomena of surgical shock are typically illustrated in the case reported at the beginning of this paper, and are almost exactly reproduced in a case within the last month I was hastily called in consultation by Dr McMurtry, who had an hour previously delivered his patient of her seventh child She was 42 years of age, very robust and an illustration of perfect health By overtaxing her strength in household duties labor was induced two or three hours in advance of maturity Labor came on rather precipitately, but aside from this, it was completed without an untoward symptom She informed her attendant that in her last confinement the hæmorrhage was alarmingly profuse Immediately after the expulsion of the fœtus, and before the placenta had been detached, Dr McMurtry noticed the pallor of countenance and the complete relaxation of the whole muscular system The heart was beating rapidly, could not be counted, and the second sound was obliterated The patient lay quietly, breathed easily, and presented a typical picture of surgical shock A noticeable feature was the very marked improvement at times of the tone of the circulation, and its sudden recession within a few seconds' time There were no convulsions, no loss of blood, and the only complaint was that of præcordial distress Dyspnœa came on gradually, and in exactly five hours from delivery she quietly passed away This was an almost exact reproduction of my first experience, and differed only in this, that in the first patient restlessness and great distress were prominent, and in the second they were not present at all

In the absence of any demonstrable evidence of

the presence of air in the veins or of embolism, we must attribute death to that mysterious complexus of symptoms we include in the general term of *shock*. Pathological investigation refers the phenomena of shock to a reflex paralysis of the vaso motor or splanchnic nerves, whereby the mass of the blood recedes from the surface and collects in the thoracic or abdominal viscera. Through this same influence the heart is enfeebled, and soon overworked by its ineffectual efforts at ridding itself of its constantly increasing burden, and finally yields to the pressure and ceases to contract. The condition is favorable to coagulation, and doubtless this often occurs.

In addition to the pains and exhaustion of child birth, mental emotions have no small part in the production of a state of the nervous system favorable to shock. The patient had been for a year brooding over a domestic tragedy, and made frequent visits to the State Prison to see her son, who was undergoing a sentence for murder. She was greatly humiliated, lost sleep, and was ready at all times to give way to the most wretched despondency. How great a part this circumstance had in bringing about the calamity we are unable to say. Lusk tells us that the homesick prisoner of war and the conquered soldier who is left on the field of battle yield with readiness to shock and perish from the most trivial wounds. We cannot ignore these facts, and must give prominent place in our classification to that at present unexplainable something we call shock.

Unless the case reported at the beginning as an introduction was one of embolism, I have never encountered the accident in my midwifery practice. As an autopsy was denied, the diagnosis is made solely upon the symptoms above detailed, and moreover, I cannot find a single report of an embolus having been discovered in an autopsy of a patient dying during or immediately after delivery.

It has been assumed for a number of years that the blood is in a favorable state for coagulation during pregnancy. This theory has been strongly maintained by Barker, Playfair, Meigs and others, and in clinical experience many striking facts have arisen to support this belief. Dr. Mary Putnam Jacobi reported a case similar to my first one to the New York Pathological Society, and exhibited the heart containing the clots, which she maintained were post mortem.

In all the cases reported the feeble circulation was always the first symptom to cause alarm, and, if coagulation takes place it is the result of this enfeebled circulation, and not its cause. The fact remains that numbers of puerperæ die and with symptoms as detailed above in these three cases. While there is great similarity in them, yet they are widely apart in many important particulars.

Now, it is not sound pathology to ignore these facts and to banish as unworthy of consideration a well established pathological condition, simply because in the days of ignorance the terms exhaustion and shock were indiscriminately employed to explain a multitude of cases which, with our present enlightenment, we know are due to the entrance of air into the circulation, and to pulmonary embolism. As the nervous organization of woman loses in powers of resistance as the penalty of a higher civilization and of artificial refinement, it becomes imperatively necessary for the physician to guard her from the dangers of excessive and too prolonged suffering. I have always urged the principle and have carried it out in practice, that the exquisite torture to which many women are subjected is unnecessary. The impression made upon a sensitive organization by prolonged and constantly increasing pain can and does result in damage to the central nervous system.

In a measure, then, we can diminish the liability to danger from shock and exhaustion by timely and judicious interference, to danger from entrance of air into the circulation by the position of the patient, the means employed in assisting uterine dilatation, but in the prevention of clot formation, in the light of our present pathological knowledge, we are powerless, and in the presence of either of these conditions we must stand helplessly by and say with Winckel, that the only thing remaining for the physician to do is to seek out the cause of death.

DISCUSSION

Dr. I. N. Rosenthal, of Fort Wayne, Ind.: Sudden deaths after parturition are fortunately very seldom, but they are nevertheless very terrible, and I hope to be excused if I report a case in full. A multipara was taken sick and confined about 8 P.M., and about 3 A.M. I was called by the attending physician. The lady was in a perfect frenzy of anxiety because the attending physician had stated to the parties that there was something wrong. I found a second fœtus in shoulder presentation, with no worse symptoms than would naturally be expected in a case of malposition or where labor was not normal. I turned the child without trouble, and after delivery the lady seemed to be perfectly happy and satisfied, and expressed feelings of gratitude and comfort. Within a half hour the attending physician and myself noticed the pulse becoming less, the lady felt as if she was fainting, but there were no other symptoms, the uterus was perfectly contracted, and no sign of hæmorrhage. The pulse continued to become weaker, and in less than half an hour the woman collapsed and death took place. What was the cause of death if it was not thrombosis or embolism? It certainly was not shock, there was no sign of sufficient shock for at least half an hour after delivery.

Dr. W. W. Grant, of Davenport, Iowa: There is one point of much interest in connection with this case which I do not think ought to be passed by unnoticed, and that is, whether we are as helpless as the author of the paper would indicate. It seems to me that in these cases of accidental hæmorrhage due to separation of the placenta, as distinguished from placenta prævia, it is just one of those slight hæmorrhages that come on previous to delivery. The hæmorrhage in this case was probably the cause of premature death, and is a very interesting point. These cases are not so uncommon, and it is a question whether we cannot do something to arrest that condition. I have recently had such a case, and have treated other cases, and I think something can be done to avert the embolism, whether it is from

air or blood, and that is the administration of ergot, even before labor in this case, I have done it systematically, have given ergot not in large enough doses to produce labor, but enough to produce a gentle, firm contraction of the uterus I gave it recently for three weeks, 25 drops Squibbs' extract of ergot That contraction is worth something even after delivery

DR W H WATHEN, of Louisville, Ky I was certainly very much interested in this excellent paper read by Dr Dunlap I was specially interested because I have had a misfortune somewhat similar recently, in which a lady was sent to me from a distance who had become illegitimately pregnant She came of a very good family, was very much depressed, and in fact had no desire to live She passed through her delivery, and in the second stage of labor the uterus contracted down and the placenta was removed without difficulty, and it contracted again In about five minutes hæmorrhage began and the uterus relaxed I introduced my hand very quickly and grasped the uterine cavity and the hæmorrhage ceased The woman lost probably eight or ten ounces of blood A hypodermic injection of ergot was given immediately We had no warm water, nothing but a solution of chloride of iron, one part iron to ten warm water The hæmorrhage immediately ceased, the uterus contracted down firmly, and remained contracted The woman did not bleed any more, her pulse was perfectly good, her respiration normal, no disturbance of any sort whatever In probably half an hour after this I felt the pulse and it was getting rapid, it had been 70 to 80, then 90, then it went up to 100, finally she was gasping for air, could not breathe, the pulse 110, and it finally disappeared altogether I gave hypodermic injections of whiskey, but she gradually grew worse, rallied again with external heat, grew worse, and in an hour died, remaining conscious until probably ten minutes before death This is a case in which it is difficult to understand the cause of death It certainly was not from shock, there was no apparent shock during labor or immediately after, and no apparent shock after hæmorrhage had ceased I could not account for it by air in the blood vessels, because if air had got in it would have been when the injection was used, and symptoms would have been manifested immediately I accounted for it by pulmonary clot, embolism, where probably the clot from the uterus was by some means taken up through the vena cava to the heart and then to the lungs If it was not a pulmonary embolism I am unable to account for it

---

WOUND DRESSING SOME NOTIONS ACCEPTED AND SOME UNDER DISCUSSION

Read in the Section on Surgery and Anatomy, at the Thirty Eighth Annual Meeting of the Am Medical Association

BY GEORGE E STUBBS, A M, M D,

PROFESSOR OF SURGICAL PATHOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE, AND SURGEON TO THE CHARITY AND THE MEDICO-CHIRURGICAL HOSPITALS, OF PHILADELPHIA

In presenting a few thoughts upon the subject of wound dressing, I do not feel that I need to apologize on account of the triteness of the subject, since every surgeon of experience has ideas peculiar to himself on this practical subject, which should be cast in the common fund of information, to add if possible to the heritage of knowledge, which we have jointly received from the honored surgeons of the past I must, however, disclaim the idea of offering any notions that are very original, though I hope that from an experience of some twenty five years of military and civil surgery that I may present some ideas which may interest for a few moments, if they do not edify

But even if one cannot always present new and original ideas, as the result of patient, methodical research, it is often of great advantage both to the reporter and the profession to whom he reports, for the physician to take time to put himself upon a point of observation, and take a general view of ground gone over and of prospects ahead In doing this I am impressed at once with the rapidity of professional unification Where less than a generation ago surgeons in each country were a law unto themselves in the matter of surgical tenets, now, so closely do electricity and steam unite the World that the surgeons of every land are our brethren, and if Horsley of England removes a tumor from the brain, and his diagnosis and prognosis are both thereby verified, we clap him on the shoulder, in spirit at least, and hail him as our brother, if Billroth boldly takes the risk and operates for cancer of the pylorus, we fraternally admire his courage and zeal, and resolve to emulate his example as occasion demands, and when Keith presents his latest and best statistics in ovariotomy, we are ready to cry "bravo!"

With this diversion from my subject, let me now remark, *firstly*, that our ideas upon the subject of wound dressing are constantly changing, I find, on referring to many works of standard excellence in surgery, which grace my library, including the three immense tomes of the "Surgical History of the Rebellion," that many of the terms now constantly in use in our surgical literature, our surgical clinics and the surgical wards of our hospitals, and likewise in every meeting and discussion of well read medical men, are not even mentioned, indeed, such is the rate of progress, especially in the line of bacteriology, that surgical works published but five or ten years ago are now considerably behind the times

Most of the principles, however, of such works are still as true as ever, so far as experience has yet proven, just as we may still assert, that many of the principles handed down to us from Hippocrates, such as the application of bandages, and, in all severe wounds, rest, a strict regimen, and an easy position for the limb, the rejection of oil and all moist applications except poultices in certain cases

If I take up a certain standard work on surgery, I find under the general heading of wounds, the indications given thus

1st "The arrest of hæmorrhage," which probably all surgeons now would agree to at once, although Hippocrates believed in letting the blood flow copiously when situated upon the limbs or penetrating the cavities of the body

2nd The removal of foreign bodies, and then comes

3d The apposition of divided parts, for which the surgery of to day would substitute *antiseptic washing of the parts*, putting the injunction mentioned as the *fourth* in order of sequence, and then comes the general wise injunction "The use of such measures as will cooperate with Nature to the fullest extent in the repair of the damage"

This last phrase is so long headed in its foresight as to include all the bacteriological and other improvements, that all the Kochs, Pasteurs, Sternbergs and Cheynes are likely to invent in the next thousand years and is therefore admirable

But although all the surgeons as a rule believe in arresting all hæmorrhage before closing the wound, yet one point in regard to the blood is under discussion now, namely, is it best to leave a wound under a moist blood clot? From a careful review in the May number of *The Annals of Surgery* of Dr M Schede's (Hamburg) article in the *Archiv fur klin chir*, 1886, Bd 24, Hef, by Dr Browning, of Brooklyn, I learn that Dr Schede has summed up 241 such operations, including, *e g*, 40 joint resections, 18 excavations of tubercular foci in bone with free opening into relatively healthy joints, 30 total removals of small cheesy bones, 29 necrotomies, 20 Phelps' operations, 24 extirpations of tumor sacs, etc His procedure is the customary one as far as constriction, careful antisepsis with the one to one thousandth bi chloride of mercury solution, and complete removal of all diseased tissue It differs from the customary method in leaving one or two openings above instead of below in order to *collect* any oozing blood, and making a Neuber's button hole where the conditions demand The skin was approximated regardless of apposition of deeper parts In some cases, as in Phelps' operation, the wound was not closed No drainage was used but an imperforated silk covering, which should extend several centimetres beyond the wound edges This must fit the skin nicely, and serves the double purpose of insuring the filling of the wound, then also prevents any sucking up of the wound clots No other imperforate layer but gauzes, cotton, moss, sacks, and as perfect rest as possible Under such treatment, prompt coagulation, fibrination and cicatrization takes place The blood under such conditions fills in all angles and cavities Small bone cavities heal in from twelve to fourteen days, larger ones in three to six weeks He avoids putting foreign matter in wounds but uses catgut on occasion To keep the bones in place, he uses hard rubber splints, softened by boiling water to fit the part, and loosens the constriction for a time before bandaging, and ligates bleeding vessels He expects a good result, and accordingly does not remove a dressing though soaked in blood, if it dries If the soaking persists, he opens No constitutional disturbances occur except occasionally an aseptic fever for two or three days

It is said that the results were notably good The method has not been applied to operations on the hip joint nor on the soft parts of the body, except in tenotomies and deep lacerations with retraction Complete antisepsis is a necessity, where this seems questionable he fills the cavity with antiseptic material as gauze or bismuth, and waiting for granulations, these may then be slightly scraped, and the resulting flow of blood be utilized according to the principles already enunciated

Imperfect results arise from (1) flow of blood being insufficient to fill wound This is to be avoided by care at first (2) From fungus breaking down of the cicatrix (3) From any septic infection Foreign substances or sequestra naturally lead to a resulting fistula It is said that the use of antiseptic powders is not permissible in this method as the carbolic acid would likely be less satisfactory than the bichloride

We are accustomed to consider the union by what has been called first and second intention as two different and distinct physiological processes, but according to Zeigler these healing processes "are in principle the same" the difference being only in quantity

From time immemorial good surgeons have been accustomed to make use of the principle of specific gravity for the drainage of wounds, where possible, even using the knife boldly to that end For years drainage tubes of metal, gum or other material such as horse hair, chicken bones, or strings have been used to conduct pus out of deep cavities, in either case the appliances being made antiseptic Again sponges or iodoform gauze bags with antiseptic material for absorption purposes within, have been lowered or packed into cavities, and removed with the infiltrated fluids at short intervals

We have long appreciated the importance of correct hygienic surroundings such as pure air and water, good and easily digested food, clean rooms and bedding, and great cleanliness as to all dressings, and at this time still, many surgeons boldly assert that *cleanliness in all things* gives them, quite as good results, as are obtained by the most thorough antiseptic surgeons This is then one of the notions now under discussion Probably the large majority of the profession believe in antiseptic surgery, not Listerism *in extenso*, but careful antisepsis Yet there are those who assert that at this era in surgery, so well proved is the value of antiseptic surgery, that a surgeon should be held liable at law for damages, if, in the practice of surgery where he had failed to use antisepsis his patient was not healed

This is the bacteriological epoch in medicine, and never did surgery comprise so large a portion of the whole as now Where once our science had but the extreme injuries of the body for its field, now it halts at but few points, and perhaps I would be more accurate if I said that it halts at none

In the matter of wound dressing, the important discoveries in regard to the effect of bacteria are constantly increasing, and what at first and only a few years ago, was largely empirical practice, has now, almost, if not quite, reached the dignity and accuracy of a science Ogston has shown that all pus contains bacteria, that the more abundant the pus, the more bacteria are found The most valuable researches of Sternberg and others have show

us what agents are most effective in exterminating germs, but some of these while most effectual in killing germs, are deadly when used internally, and somewhat dangerous even in their external use We find a great diversity of views among different surgeons in different countries, and likewise among those of our own Some rely upon the bichloride solution of from 1 20,000 to 1 1000, others use carbolic acid solution, while many, as in Germany, pin their faith upon iodoform Others still use the one or the other for different purposes The opinion of surgeons, has not definitely crystalized as yet but I think it is fast doing so So rapidly are discoveries made, however, in this golden era of surgery, that we cannot forecast at all what even our immediate future may bring forth, but judging from the progress being made in this decennium, we have a right to expect great things

MEDICAL PROGRESS.

DIAGNOSIS OF SARCOMA OF THE BREAST.—In an article on "Sarcoma of the Female Breast," DR S W GROSS says

Between the spindle celled, round celled, and giant-celled there are marked similarities which render their differentiation difficult The spindle-celled, however, are characterized by their development at a comparatively early age, by the attendant suffering, by the enlargement of the subcutaneous veins, by their slow reproduction after removal, and by their long life The round-celled, on the other hand, appear, as a rule, at a comparatively late age, and are painless, but the skin is liable to be discolored and ulcerated, and recurrence is rapid, and the duration of life is relatively short The giant-celled likewise appear late in life, but are painful, discoloration of the skin and ulceration are also common, but there is no enlargement of the veins, while irritative enlargement of the axillary glands is frequent Local reproduction is delayed longer than in the other varieties, and the duration of life is remarkable These points are set forth in the following table, in which the affinities and contrasts of the three principal varieties may be seen at a glance

	Spindle celled	Round celled	Giant celled
Average age of appearance	36 years	48 years	47 years
Appear before the 16th year	12 08 per ct	0 83 per ct	0 per ct.
Pain	60 00 "	10 81 "	43 "
Skin discolored	20 88 "	32 35 "	25 "
Ulceration	17 58 "	23 58 "	25 "
Veins enlarged	17 58 "	11 76 "	0 "
Glands swollen	6 59 "	8 82 "	37 5 "
Glands infected	0 "	2 91 "	0 "
Adjacent tissues invaded	13 18 "	17 64 "	25 "
Local reproduction	65 10 "	60 "	57 14 "
" " average date of	12 months	4⅔ months	12⅓ mos
Metastatic deposits	20 40 per ct	25 per ct	0 per ct
Average life with operation	90 months	54 months	108 mos

Between the solid and cystic varieties there are certain distinctions, which are useful in establishing a different diagnosis The former develop at about the forty-third year, the skin is discolored in 11 53 per cent, ulceration occurs in 7 69 per cent , the veins are dilated in 7 69 per cent , there is no discharge from the nipple, nor is it retracted, pain is met with in 28 per cent , the surrounding tissues are invaded by tumor elements in 11 54 per cent , the lymphatic glands are enlarged in 11 54 per cent , and infected in 1 28 per cent , recurrence ensues in 64 58 per cent , and metastatic growths are met with in 25 per cent of all instances Cystic sarcoma starts, as a rule, at the thirty-eighth year, and is not, as is asserted by many writers, most common between twenty and thirty-five years, as just as many cases occur after as before the latter age, it grows more rapidly than the solid variety, and its increase is often sudden after having remained stationary or advanced slowly for some time Now and then, after evacuation of the fluid of the superficial cysts, their solid contents can be detected by manipulation, their consistence is, as a rule, unequal, and they are more largely lobulated than the former variety The skin is discolored in 34 61 per cent , the tumor ulcerates in 18 76 per cent , the veins are enlarged in 23 07 per cent , the nipple is retracted in 6 41 per cent , and discharges fluid in 10 25 per cent , pain is experienced in 41 93 per cent , the adjacent tissues are infected in 16 66 per cent , the lymphatic glands are swollen in 5 12 per cent , but they are never invaded by tumor elements, while it recurs in 51 16 per cent , and becomes generalized in 11 62 per cent of all cases

There are no signs by which cystic sarcomata can be absolutely differentiated from cystic fibromata, with which they are so frequently confounded The latter develop earlier in life, and a discharge from the nipple is more common than in the former, but ulceration and enlargement of the veins are only one-half as frequent, and they are not attended with glandular enlargement or malignant features It should, however, be stated that the largest proliferous cystic tumors met with in old, married multiparæ are generally sarcomata.—*American Journal Medical Sciences*, July, 1887

USE OF THYMOL.—DR FREDERICK P HENRY, of Philadelphia, says Following the suggestion of Martini, in the *Annali Universali di Medicina e Chirurgia* for February, 1887, I have recently prescribed thymol in a number of cases of intestinal diseases, catarrhs, acute and chronic, and typhoid fever, with the result of convincing me that it is a valuable adjuvant to our treatment of such affections I do not attach any particular significance to the fact that all the cases of typhoid fever, ten in number, to which I have thus far administered the drug, recovered, but my conviction that the course of the disease was most favorably modified by the treatment was shared by the resident physicians, by practitioners who visited the hospital for the purpose of seeing the cases, and last, and perhaps not least, by experienced nurses

The benign course pursued by these cases was especially evident when contrasted with that of an equal number treated without thymol during the first half of my hospital term The favorable effect of the drug was evinced by a steady descent of the temperature, by a gradual diminution in the daily number of stools, by the absence of mental excitement, and,

most conspicuously, by the clean, moist tongue presented in every instance One case caused some anxiety for a few days after his admission, on account of the presence of decided tympany and general abdominal tenderness, but these ominous signs gradually disappeared

I have also administered thymol, with good results, to several cases of intestinal catarrh, of which one is worthy of some detailed account Mary S , æt. thirty-six, married, was admitted to the Episcopal Hospital on May 14, 1887 She was pale, thin, and anæmic Seven years ago, after removing to Philadelphia from the country, she had an attack of "diarrhœa" (dysentery?) with from fifteen to twenty stools a day, in spite of treatment Defecation was painful, with marked tenesmus, and the dejecta were thin and streaked with bloody mucus Gradually the number of passages were reduced to from five to six per diem, and, for nearly seven years, notwithstanding treatment by several physicians, this has been the daily average Soon after admission she was given thymol gr x , ter in die, and the next day the number of stools was reduced to three A week later, she had a well-formed stool every second day, and expressed herself as feeling better than at any time during the past seven years On July 1, when my term of service expired, she was well, so far as the diarrhœa was concerned, but was still somewhat anæmic

The medicinal use of thymol is based upon its well-known antiseptic properties, and its action in the cases under consideration was favored by its great insolubility, which enables it to reach the intestine, mingle with its contents, and neutralize the toxic ptomaines that are formed in great quantity in catarrhs of the gastro intestinal tract In the opinion of many authorities, it is to the absorption of large quantities of these toxic products of fermentation and putrefaction that the so called typhoid symptoms are largely due These opinions do not rest solely upon theory, for it is found that, during the administration of thymol, phenol, which is one of the most constant products of intestinal putrefaction, and is almost entirely eliminated with the urine, is no longer found in that excretion

I have always prescribed the thymol in pill, of which the best excipient is medicinal soap, and, so far, have not given more than thirty grains in twenty-four hours—two two and a half grain pills every six hours This is a small dose, but I have seen no reason to increase it This may be done, however, with perfect safety, and, perhaps, with still better results It has been administered, with brilliant results, by Bozzolo, in cases of anchylostomiasis, in doses of from ten to twelve grams (two and a half to three drachms) per diem

The only case in which I found the drug to produce any unpleasant effect—slight digestive disturbance—was that of a woman with advanced phthisis, chronic diarrhœa, and who was, besides, the host of a tapeworm Thymol has been found to be an excellent tenifuge by several Italian observers, and it was for this purpose that I prescribed it in the case last mentioned The woman had voided no fragments of the worm for two weeks, and it was a question whether the parasite had been entirely expelled Although but a few doses of the thymol were tolerated, they were quickly followed by the expulsion of several fragments of the worm

Martini, whose experience with thymol has been large, has only found it give rise to unpleasant symptoms—delirium and stupor—in one case, that of a girl, æt 14, to whom 30 grains had been given in the course of two hours, the symptoms were transient, the treatment was resumed, and the case, one of typhoid fever, recovered without further mishap

Dr D J Milton Miller has continued the use of thymol in the medical wards of the Episcopal Hospital since he took charge of them on July 1, and writes as follows "Generally speaking, my success with thymol, in typhoid fever, has been most satisfactory The cases do seem to run a more favorable course than usual, as shown by lower temperature-range, less diarrhœa, the absence of complications, and even a shorter duration of fever "—*Medical News*, Sept 3, 1887

EUGENOL AS AN ANTISEPTIC —According to GEO H OCHSE, Ph G , eugenol, the principal component of oil of cloves, is found also in *Myrtus pimenta (Pimenta officinalis*, Lindley), *Amomis acris*, Berg *(Myrtia acris*, DeCandolle), *Canella alba*, Murray, *Dicypellium caryophyllatum*, Nees, and in *Ravensara aromatica*, Sonnerat Eugenol, a phenol like compound, is insoluble in glycerin and water, and is obtained as a residue when oil of cloves is subjected to distillation with strong caustic alkalies After the so-called light oil of cloves is distilled off, sulphuric acid or phosphoric acid is added, and by continuing the distillation without access of air eugenol is obtained Eugenol is an oily, colorless liquid, possessing the odor and taste of the oil of cloves to the highest degree In contact with air and light it soon aquires a brown color, it boils at 247 5° C , and has a specific gravity of 1 078 at 0° and 1 063 at 18 5° C Like phenol, which it resembles very much, it has no acid reaction, does not contain the group COOH, and also forms crystallizable compounds with alkalies When heated with hydriodic acid it evolves methyl-iodide, and when fused with potassium hydrate it forms protocatechuic acid, with baryta and tin-dust it forms about ten per cent methyl eugenol When taken internally the greater part of it is eliminated by the urine, in which, however, it cannot be detected by its odor not by distillation, but if allowed to decompose, the characteristic odor is at once perceptible, and when extracted with alcohol shows the characteristic deep green coloration with ferric chloride Eugenol has been given in doses of three grams per day dissolved in alcohol and diluted in water As an antiseptic, it is superior to phenol, as a febrifuge, it is not as efficacious as quinine, salicylic acid, antipyrin, or thaline —*American Journal of Pharmacy*, March, 1887

CÆSAREAN SECTION PERFORMED SUCCESSFULLY ON A COW —DR C HAMILTON, of Ringgold, Ga , writes On the 20th day of April I was called some dis-

tance in the country to see a patient On my arrival I was asked by a gentleman of the house to come out to the lot as soon as I had made a prescription for his daughter, whom I had visited In the lot I found a cow in labor, and had been for about twenty-four hours On examination I found that, owing to an injury that she had received on the railroad, there was not sufficient passage for the calf Its fore feet were protruding, and there was no room for the passage of its head The gentleman insisted on saving the life of the calf, so I concluded to perform the Cæsarean section, though I had never heard of this operation having been performed on a cow, so, without the use of any anæsthetic, I immediately began the operation by making an incision a little to the right of the median line, commencing just at the edge of the mammary gland, and cutting up made an incision six or seven inches long, and the cut in the uterus as small as would admit the calf As the membranes had not ruptured, I waited a few minutes and then proceeded to rupture them and deliver the calf In a few minutes it was up, walking about I used a catgut suture in closing the cut in the uterus A few minutes after the cuts were closed the cow got up and let the calf suck There was very little swelling or suppuration during the healing of the wound The lochial discharge commenced at once and continued its usual time I directed that she should be fed on meal and bran for fifteen or twenty days I learn that she has been giving sufficient milk for the calf all the time, and at this date is doing well, running in the range with other cattle It is strange to say that the protrusion of the membranes and the contraction of the uterus at the cut was just the same as at the mouth, showing very plainly that the contractility of the uterus is in every part and direction, while the uterus was cut laterally, the contraction was great and the pains as regular as during natural labor The cow struggled but little during the operation, and what little she did seemed to assist in delivery —*Southern Medical Record*, July, 1887

STRUCTURE OF THE UTERINE ARTERY —The phenomena of sexual life in woman necessarily involve frequent variations in the blood supply to the uterus and ovaries Professor Thoma has already noted the development of connective tissue in the tunica intima of arteries in relation to the mechanical conditions of the circulation Dr Westphalen, of Dorpat, has recently examined the uterine artery in order to see how the intima is arranged in that vessel He discovered that in childhood the intima consists of endothelium and of an elastic membrane which forms folds like a ruff when the vessel is empty Between these layers he found in places some elastic and muscular fibres, but very little connective tissue At the height of sexual life, however, a very distinct and thick layer of this tissue could be detected in the intima It increased in thickness as the vessel neared the uterus, and was most marked in women who were not very young and who had borne children Similar histological conditions were detected by Dr Westphalen in the intima of the ovarian artery, but in a much less marked degree This disposition of the connective tissue in the intima must depend upon the physiological peculiarities of the part which is supplied by the uterine artery A similar histological condition has been already noted in the splenic artery, a vessel which is also distributed to an organ subject to periods of physiological engorgement Dr Westphalen's researches appear in the form of a short note in the 106th volume of Virchow's *Archiv*, pt II —*British Medical Journal*, August 20, 1887

BONE PEG IN OPERATION FOR PSEUDARTHROSIS — At a recent meeting of the Paris Société de Chirurgie, a report of which appears in the *Deutsche Medizinal Zeitung*, M RICHELOT related the case of an hysterical girl, sixteen years old, with a congenital atrophy of the face, for which resection of a portion of the lower jaw was performed The fragments were united with silver wire, but the patient was restless, and the union which took place was by fibrous tissue Dr Routier subsequently drilled a hole through the fragments, excised the callus, and pegged the two parts of the bone together with a portion of the tibia of a calf, which had been steeped for twenty-four hours in a solution of 1 part of corrosive sublimate in a mixture of 900 parts of distilled water and 100 of alcohol Bony union followed, with only a slight asymmetry, and the patient could eat better than before No disturbances of the dental nerves were observed —*The New York Medical Journal*, August 27, 1887

INTRAPERITONEAL HÆMORRHAGE, REOPENING OF THE ABDOMEN —MR HENRY W FREEMAN, reports the case in which the bleeding came from a rent in the pampiniform plexus of the broad ligament, between the uterus and the stump of the clamped pedicle The rent was probably due to traction on the tumor in lifting it out of the pelvis before the pedicle was clamped No bleeding occurred when the pedicle was drawn upwards, owing to mechanical closure of the rent by the traction thereby exercised on the broad ligament He directs special attention to the fact that he was enabled to establish his diagnosis of secondary hæmorrhage (and thus save the patient's life) by means of the glass drainage tube which he had fixed between Douglas' pouch and the lower angle of the abdominal incision —*Lancet*, June 4, 1887

TREATMENT OF DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA —KOCHER advises excision of the fibrous constricting tissue This should be done through a single longitudinal incision, and in old cases where the cutis has become so intimately adherent to the underlying fibrous bands, a piece of the former should be excised To attempt to excise under these conditions only the contracting tissues would leave the overlying skin too thin, and thus the wound would heal by granulation, rather than by primary union, which is essential Gersuny has also practiced this operation with very good results —*Centralbl f Chirurgie*, No 27, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

THE CONGRESS IN WASHINGTON

By the time this issue of THE JOURNAL reaches its readers the work of the Ninth International Congress will be concluded The dispatches from Washington state that the prospects are good in all respects for the Congress

On Monday at 11 A M, DR HENRY H SMITH, Chairman of the Executive Committee, called to order a large assemblage in Albaugh's Opera House, and after reviewing the history of the manner in which the Congress came to meet in America, introduced HON GROVER CLEVELAND, President of the United States, who said

"I feel that the country should be congratulated to day upon the presence at our Capital of so many of our own citizens and those representing foreign countries, who have distinguished themselves in the science of medicine and are devoted to its further progress My duty on this occasion is a very pleasing and a very brief one It is simply to declare that the Ninth International Medical Congress is now open for organization and for the transaction of business"

The Chairman of the Executive Committee then nominated the gentlemen agreed upon by the Committee to be officers of the Congress "For the high office of President of the Congress," he said, "the Committee unanimously nominate to you one widely known as a scientific practitioner, an able teacher, and medical author, Dr Nathan Smith Davis, of Chicago" Dr Davis having been elected by acclamation, he was escorted to the Chair by Dr Francesca Durante, of Italy, and Deputy Surgeon General Jeffrey A Marston, of her Britannic Majesty's Army The other officers were then elected as nominated, the Secretary General, DR JOHN B HAMILTON, Supervising Surgeon General of the U S Marine Hospital Service read his report, and DR A Y P GARNETT, Chairman of the Local Committee of Arrangements, announced the social programme for the Congress

The President of the Congress then introduced HON THOMAS F BAYARD, Secretary of State, who said
